

Multimodal Sensor Front End

FEATURES

- ▶ Optical channel
 - ▶ 4 input channels with multiple operation modes for various sensor measurements
 - ▶ Dual channel processing with simultaneous sampling
 - ▶ 12 programmable time slots for synchronized sensor measurements
 - ▶ Flexible input multiplexing to support single-ended sensor measurements
 - ▶ 4 LED drivers, 2 of which can be driven simultaneously
 - ▶ Flexible sampling rate from 0.004 Hz to 9 kHz using internal oscillators
 - ▶ SNR of transmit and receive signal chain: 117 dB (with off-chip filtering)
 - ▶ AC ambient light rejection: 78 dB up to 100 Hz
 - ▶ 400 mA total LED peak drive current
 - ▶ Individual ambient light rejection DAC at TIA input with 9-bit control up to 300 μ A
 - ▶ Individual LED dc cancellation DAC at TIA input with 7-bit control up to 190 μ A
- ▶ ECG channel
 - ▶ 0.75 μ V rms RTI noise at diagnostic filter bandwidth (150 Hz)
 - ▶ High input impedance: 3 G Ω
 - ▶ Accepts up to 1.2 V of dc differential input range
 - ▶ Common-mode rejection ratio: 116 dB
 - ▶ Two-electrode and three-electrode configurations
 - ▶ AC lead off detection and dc lead off detection
- ▶ BIA channel
 - ▶ Low power, high accuracy excitation path
 - ▶ Configurable output frequency up to 250 kHz
 - ▶ Sine wave excitation with a 12-bit DAC
 - ▶ High accuracy with large imbalance contact impedance
 - ▶ Configurable receive filters with low noise design
 - ▶ Complex impedance measurement engine
 - ▶ Supports both external calibration and internal calibration
- ▶ SPI communications supported
- ▶ 640-byte FIFO

Analog Devices is in the process of updating documentation to provide terminology and language that is culturally appropriate. This is a process with a wide scope and will be phased in as quickly as possible. Thank you for your patience.

APPLICATIONS

- ▶ Wearable health and fitness monitors: heart rate, heart rate variability, SpO₂, body impedance analysis, hydration, cuffless noninvasive blood pressure
- ▶ Home patient monitoring
- ▶ Industrial monitoring: particle and aerosol, gas, and conductivity detection

GENERAL DESCRIPTION

The ADPD6000 is a highly integrated analog front end (AFE) designed for measuring various vital signals.

The optical channel is designed as an optical transceiver, stimulating up to four light emitting diodes (LEDs) and measuring the return signal on up to four separate current inputs. The signal chain rejects signal offsets and corruption from asynchronous modulated interference, typically from ambient light, eliminating the need for optical filters or externally controlled dc cancellation circuitry.

The electrocardiography (ECG) signal acquisition is designed to support low noise, diagnostic level measurement in the presence of a variety of interferers. The ECG signal chain has a number of complementary features supporting ECG measurement, such as driven reference for common-mode rejection and lead off detection to identify a fallen electrode.

The body impedance analysis (BIA) signal chain is designed for body impedance measurement with a configurable excitation path and measurement path. A 12-bit digital-to-analog (DAC) is used in the excitation path to generate the sinusoid wave and high precision measurement, with configurable filters used to measure the body response of the stimulus.

The data output and functional configuration use a serial port interface (SPI) on the ADPD6000. The control circuitry includes flexible LED signaling and synchronous detection, digital filters, digital wave generators, and configurable filters.

The ADPD6000 is available in a 2.6 mm \times 2.6 mm, 0.4 mm pitch, 36-ball wafer level chip scale package (WLCSF).

ABSOLUTE MAXIMUM RATINGS

Table 5. Absolute Maximum Ratings

Parameter	Rating
AVDD to AGND	-0.3 V to +2.2 V
AVDD3 to AGND	-0.3 V to +3.9 V
DVDD to DGND	-0.3 V to +2.2 V
IOVDD to IOGND	-0.3 V to +3.9 V
GPIOx, MOSI, MISO, SCLK, \overline{CS} to DGND	-0.3 V to +3.9 V
LEDxx to LGND	-0.3 V to +3.9 V
Junction Temperature	150°C

Stresses at or above those listed under Absolute Maximum Ratings may cause permanent damage to the product. This is a stress rating only; functional operation of the product at these or any other conditions above those indicated in the operational section of this specification is not implied. Operation beyond the maximum operating conditions for extended periods may affect product reliability.

THERMAL RESISTANCE

Thermal performance is directly linked to printed circuit board (PCB) design and operating environment. Close attention to PCB thermal design is required.

θ_{JA} is the natural convection junction to ambient thermal resistance measured in a one cubic foot sealed enclosure. θ_{JC} is the junction to case thermal resistance.

Table 6. Thermal Resistance

Package Type	θ_{JA}	θ_{JC}	Unit
CB-36-10 ¹	42.15	0.98	°C/W

¹ The thermal resistance values are defined as per the JESD51-12 standard.

ELECTROSTATIC DISCHARGE (ESD) RATINGS

The following ESD information is provided for handling of ESD sensitive devices in an ESD protected area only.

Human body model (HBM) per ANSI/ESDA/JEDEC JS-001.

Charged device model (CDM) per ANSI/ESDA/JEDEC JS-002.

Machine model (MM) per ANSI/ESD STM5.2. MM voltage values are for characterization only.

ESD Ratings for ADPD6000

ESD Model	Withstand Threshold (V)	Class
HBM	2000	2
CDM	750	C2B
MM	100	Not applicable

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

THEORY OF OPERATION

INTRODUCTION

The ADPD6000 is a multimodal, vital signal monitoring AFE that comprises three high performance signal chains: an optical measurement path (PPG), ECG measurement path, and BIA measurement path.

The PPG measurement path works as a transceiver that supports up to four LEDs and four photodiode inputs. The current on the LEDs is programmable from two 7-bit LED drivers. The receiver path provides two high performance readout channels that can sample simultaneously and can be configured separately. Two high performance current DACs (IDACs) are implemented in each channel to provide first class ambient light suppression and large dynamic range in different application scenarios.

The ECG measurement path offers a high input impedance, low noise, high dynamic range solution to allow high quality ECG signal acquisition in wearable devices. Both DCLO detection and ACLO detection are integrated to guarantee proper detectability.

The stimulus in the BIA path offers a sine wave with various options for frequency, amplitude, and phase to make the ADPD6000 suitable for measurement in different scenarios. A low noise TIA, programmable gain amplifier (PGA), filter, and ADC are integrated in the receiver channel to provide high performance impedance measurement. Direct digital synthesis (DDS) and discrete Fourier transform (DFT) engines are also integrated in this path.

An internal state machine allows flexible control of these three measurement paths. The acquisition data can be stored in a 640-byte FIFO.

TIME SLOT OPERATION

An internal configurable controller handles the operation of the ADPD6000. This controller generates the timing needed to generate sampling regions comprising combinations of the three measurement paths and sleep periods. To facilitate the use of multiple signal chains, multiple time slots handle the access to different transmitters or receivers.

The system is characterized by the ODR, which determines the repetition periodicity of each enabled time slot. The enabled time

slots are repeated at the time slot rate configured by the TIME-SLOT_PERIOD_x bits.

There are 19 time slots in the ADPD6000, as shown in Figure 26.

Each enabled PPG and BIA time slot is repeated at the time slot rate, followed by an ultra low power sleep period.

ECG_TS is the ECG time slot. The operation of the ECG signal chain is not in time slot fashion. After the ECG time slot turns on, the ECG signal chain runs until the system stops. However, the ECG signal chain output data is synchronized to the FIFO with this time slot rate.

Following the ECG time slot, there are 12 PPG time slots (PPG_TSA to PPG_TSL). Each PPG time slot allows the creation of one or more LED pulses and modulate pulses, as well as the acquisition of the photodiode or other device current based on that stimulus. The operating parameters for each time slot are highly configurable.

The last six time slots are the BIA time slots (BIA_TSA to BIA_TSF). Each BIA time slot allows the excitation voltages, frequencies, and receiver configurations to facilitate accurate body impedance measurement.

Equation 1 determines the sampling rate (time slot rate), as follows:

$$\text{Sampling Rate} = \text{Timer Clock Frequency (Hz)} / \text{TIMESLOT_PERIOD}_x \quad (1)$$

Table 9. Sources of Low Frequency Clock (LFCLK) and Timer Clock¹

THEORY OF OPERATION

OPTICAL SIGNAL CHAIN

The optical signal path stimulates up to four LEDs and measures the return signal on up to four separate current inputs. Twelve optical time slots enable 12 separate optical measurements per sampling period.

The analog inputs can be driven single-ended or in differential pairs. The four analog inputs can be multiplexed into a single channel or two independent channels, enabling simultaneous sampling of two sensors.

The optical signal chain consists of a TIA, an integrator that can also be configured as a buffer depending on the register setting, and an ADC. The digital block provides multiple operating modes, programmable timing, and block averaging.

Four independent LED drivers are provided that can each drive up to 200 mA. Two LED drivers can be enabled in any time slot and can be programmed from 1.5 mA to 200 mA monotonically, with a 7-bit register setting. The LED drivers enabled in any time slot can provide a combined maximum LED current of 400 mA.

When making optical measurements, the ADPD6000 provides 100 dB of ac ambient light rejection using a synchronous modulation scheme with pulses as short as 1 μ s. Ambient light rejection is automatic without the need of external control loops, dc current subtraction, or digital algorithms.

The LED driver is a current sink and is independent from the LED supply voltage and the LED type. The optical measurement path produces a high SNR for relatively low LED power, while greatly reducing the effect of ambient light on the measured signal.

Analog Signal Path

The analog signal path of the optical signal chain consists of four current inputs that can be configured as single-ended or differential pairs into one of two independent channels. The two channels can be sampled simultaneously for applications that require instantaneous sampling of two sensors.

Analog Input Multiplexer

The optical signal chain supports four analog input pins. Each input can be used as a single-ended input or as part of a differential pair. [Figure 27](#) shows a single representation of the input switch matrix, which allows a programmable connection to the two optical channels. Each pair of inputs has a duplicate of this multiplexer: IN1 and IN2, and IN3 and IN4. The connections are programmable per time slot.

The PAIR12 and PAIR34 bits select whether the matching input pair is used as two single-ended inputs or as a differential pair. This selection is valid for all active time slots. The INP12_x and INP34_x bits specify whether the input pair is enabled during the corresponding time slot and, if enabled, which input is connected to which optical channel.

The sleep conditions are used for any inputs that are not enabled. Sleep conditions are determined by the INP_SLEEP_12 and INP_SLEEP_34 bits, which specify the state for the input pairs during sleep and when the inputs are not active. Inputs are only considered active during the precondition and pulse regions for time slots where they are enabled.

Preconditioning of the sensor connected to the input is provided to set the operating point at the input before sampling. There are several different options for preconditioning determined by the PRECON_x bits. The PRECON_x bits are provided for each time slot to specify the precondition for enabled inputs or input pairs during the corresponding time slot. Preconditioning options include floating the inputs, VC1, VC2, input common-mode voltage (V_{ICM}), internal voltage reference signal for the TIA (TIA_V_{REF}), TIA input, and shorting the input pair. The preconditioning time at the start of each time slot is programmable using the PRE_WIDTH_x bits. The default preconditioning period is 8 μ s.

The block diagram in [Figure 27](#) shows the bias levels that can be switched into the input connections during sleep and preconditioning. These connections are not available during the sampling phase of a time slot in which the input is selected.

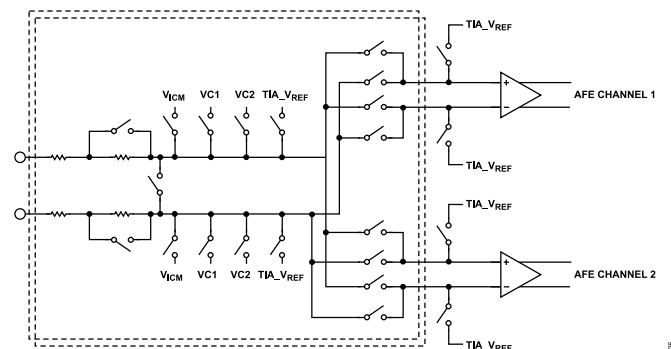

Figure 27. Switch Matrix Block Diagram

Ambient Light Cancellation

The ADPD6000 has three modes to perform ambient light cancellation, as follows:

- ▶ Coarse tuning only
- ▶ Coarse and fine tuning loop
- ▶ External microcontroller unit (MCU) control

Coarse tuning only mode and coarse and fine tuning loop mode are automatically controlled by the ADPD6000 without any software assistance. External MCU control mode allows tuning the ambient light rejection through an external algorithm.

Use the AMBIENT_CANCELLATION_x bits to choose the mode.

Coarse tuning mode works at the beginning of each PPG time slot. This mode measures the ambient light level and sets the ambient DAC code. This circuitry needs 48 μ s to complete these activities and determine the baseline of the ambient DAC. Afterward, the

THEORY OF OPERATION

PPG channel can start normal operation—for example, if in digital integration mode, the PPG receiver channel can start to take dark samples. This ambient baseline is used in the time slot if coarse tuning only mode is enabled.

If coarse and fine tuning loop mode is enabled, the coarse tuning circuit works the same way as in coarse tuning mode. However, the ambient DAC code updates after each dark sample measurement.

Select these two modes with the `AMBIENT_CANCELLATION_x` bits for system level design flexibility.

Coarse loop mode makes the measurement to find the accurate value of the ambient current. Then, the ambient DAC subtracts the ambient current at the beginning of the signal chain so that it does not corrupt the PPG signal measurement.

Both analog integration mode and digital integration mode can perform coarse loop ambient rejection.

The fine tuning loop updates the ambient information after each dark sample measurement. This feature is available only in digital integration mode.

The MCU mode allows the user to subtract the ambient current. The `DAC_AMBIENT_CH1_x` and `DAC_AMBIENT_CH2_x` bits are designed to allow the user to fill in the current ambient value, and the AFE then subtracts that value from the signal chain. `DAC_AMBIENT_CH1_x` and `DAC_AMBIENT_CH2_x` are 9-bit fields, with each LSB representing a 0.6 μA step in a 0 μA to 300 μA range.

LED DC Cancellation

Besides the ambient DAC, there is another IDAC at the input of each signal chain. This IDAC is used to subtract the unwanted dc component in the reflected LED to increase the dynamic range of the receiver channel.

These two IDACs are controlled by the MCU only. The `DAC_LED_DC_CH1_x` and `DAC_LED_DC_CH2_x` bits control the LED dc canceling, 7-bit IDAC with full scale.

The LED dc subtraction feature is available only for digital integration mode.

A certain amount of dc current can be subtracted from the AFE based on the top level optical and system design. `DAC_LED_DC_CH1_x` and `DAC_LED_DC_CH2_x` are 7-bit fields, with each LSB representing a 1.5 μA step in a 0 μA to 190 μA range.

LED Drivers

The optical path has two LED drivers, each of which is brought out to two LED driver outputs, providing a total of four LED output drivers. The device can drive up to two LEDs simultaneously, one from each driver pair. The LED output driver is a current sink.

Figure 28 shows an example of a single LED driver output pair.

NOTES
C_{VLED} IS THE BYPASS CAPACITOR.

Figure 28. LED Driver Output Pair

The LED driver output pins (LED1A, LED1B, LED2A, and LED2B) have a maximum allowable pin voltage of 3.6 V. Any voltage exposure over this rating affects the reliability of the device operation and, in certain circumstances, causes the device to cease proper operation. The voltage of the LED driver output pins must not be confused with the supply voltages of the LEDs. V_{LEDx} is the voltage applied to the anode of the external LED, whereas the LED output driver pin is connected to the cathode of the external LED. The compliance voltage is the amount of headroom voltage at the LED driver pin, measured with respect to ground, required to maintain the programmed LED current level. The compliance voltage is a function of the current required.

ECG SIGNAL CHAIN

The ECG channel measures the differential voltage across two electrodes to create a lead measurement. The output of this channel is a 24-bit digital word representing the measured ECG voltage. The maximum input differential signal is ± 1.2 V, and the LSB size is 286 nV. The output data rate can be 250 SPS, 500 SPS, 1 kSPS, 2 kSPS, or 4 kSPS. This filter selection affects the digital processing but not the analog processing. Additionally, a 4 kHz ac lead off signal is converted by the analog ECG path and extracted in the digital domain.

The ECG channel has a dedicated ADC path with feedback arrangement to remove the dc offset presented by the ECG electrodes. The ECG channel is designed to provide a high quality ECG signal process while suppressing the large dc offset that is caused by the complex system design.

Both DCLO detection and ACLO detection are integrated to accommodate different complex lead contact conditions to provide reliable lead information.

The RLD pin is designed to better bias the human body potential to avoid interference.

ECGIP and ECGIN are the signal inputs for the ECG channel, and they must be connected to the input leads. The RLD pin must be connected to the reference lead.

THEORY OF OPERATION

ECG Main Signal Chain

Figure 29 shows the ECG main signal chain diagram.

Figure 29. ECG Main Signal Chain Diagram

DCLO Detection

The DCLO circuit injects a small programmable dc current into each input electrode and monitors the resulting electrode voltage. Figure 30 shows the DCLO detection diagram.

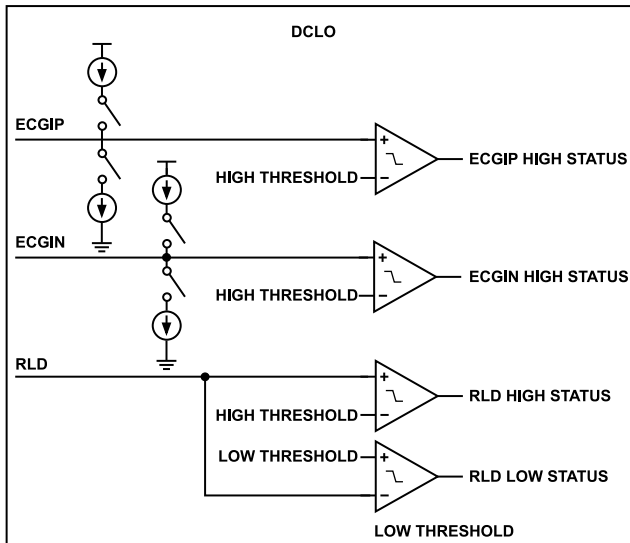

Figure 30. DCLO Detection Diagram

When both ECGIP and ECGIN, are properly connected, the current flow from one of the ECG inputs through the patient and into the other ECG input produces a minimal voltage shift. The fail current magnitude is common across all the ECG electrodes and programmable with a step size of 2 nA over a ± 16 nA range using the ECG_DCLO_MAG bit field to change the magnitude.

The polarity of the fail current is independent for each electrode and programmed using ECG_DCLO_POLARITY_IN and ECG_DCLO_POLARITY_IP. When an electrode connection degrades or falls off, the pin voltage of that electrode is pulled high or low depending on the programmed fail current polarity.

The DCLO detection circuit is based on each individual electrode input (ECGIP and ECGIN). The detection circuit is comparator based with independent programmable threshold levels for ECG inputs.

For each input lead (ECGIP and ECGIN), there is only one comparator with a high-side threshold. For the RLD pin, there are two comparators with a high-side threshold and low-side threshold.

These threshold limits are chosen such that all the threshold voltages cover the expected signal range. The window comparator compares the electrode input voltage with the corresponding threshold voltages. Where the voltage change on a particular electrode exceeds one of the programmed threshold voltages for that fail current, the dc resistance of the electrode contact can be determined to flag a lead off.

ACLO Detection

The ECG path has an ACLO detection circuit that can be used for lead off detection with the DCLO detection circuit to deal with different types of lead. Figure 31 shows the ACLO detection diagram.

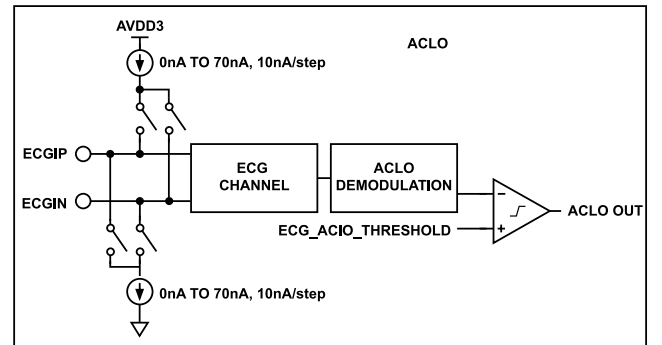

Figure 31. ACLO Detection Diagram

The ACLO method of sensing if the electrodes are connected to the patient is based on injecting ac currents into each ECG electrode and measuring the amplitudes of the resulting voltages through the ECG channel. The ECG channel must be enabled to use the ACLO function.

The magnitude of the ACLO current is programmable through the ECG_ACLO_MAG bit field. The ac current is driven out onto the ECG input paths and establishes a voltage between the ECG channel inputs where it is measured. The measured voltage is synchronously demodulated and sent through a comparator. The user can set the threshold though the ECG_ACLO_THRESHOLD bit field.

ACLO detection functions only on the ECG input pins (ECGIP and ECGIN) and is not supported for the RLD pin. A properly connected electrode has a small signal because the drive current flows into the right leg (RL). An improperly connected or dried out electrode has a larger signal as determined by a capacitive voltage divider.

THEORY OF OPERATION

Right Leg Driver

The use of a driven reference benefits overall performance by improving common-mode rejection of noise and interference from external sources, such as power line interference (50 Hz/60 Hz) or other patient connected instruments. The drive stage also acts to absorb lead fail currents injected into the ECG electrodes.

The reference electrode drive circuit senses the patient common-mode voltage and drives an inverted version back to the body, creating a negative feedback loop around the patient. The RLD amplifier uses $V_{CM} = AVDD3/2$, which centers the electrode voltages in the middle of the ADC input range. Each electrode input is buffered and fed to the RLD amplifier through a switch.

The amount of capacitance on the RLD pin affects the RLD amplifier. For best performance, the capacitance on this node must be less than 2.2 nF. In normal operation, the RLD amplifier output is applied to the RL electrode via the RLD pin and associated protection network.

The RLD amplifier can be turned off and the user can drive the RLD pin by selecting a voltage in the ECG_RLD_OUT_SEL bit field.

BIA SIGNAL CHAIN

The BIA signal chain is designed for body impedance measurement. The signal chain consists of a high frequency precision excitation loop and a measurement channel, which enables a wide capability of measurement of the different bioimpedance configurations.

The excitation loop consists of a 12-bit DAC, referred to as the high speed DAC. This DAC is capable of generating high frequency excitation signals up to 250 kHz.

The measurement channel features an ADC with input buffers, a built in antialias filter, and a PGA.

An ultralow leakage, programmable switch matrix connects the sensor to the internal analog excitation and measurement blocks. This matrix provides an interface for connecting external bioimpedance and calibration resistors. Figure 32 shows the block diagram of this BIA signal chain.

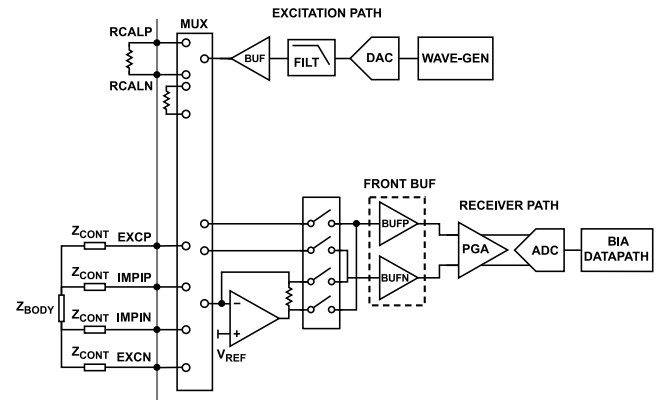

Figure 32. BIA Channel Block Diagram (Z_{CONT} Is Contact Impedance and Z_{BODY} Is Human Body Impedance)

The input multiplexer (mux) of the excitation loop is controlled by the BIOZ_TSW_x, BIOZ_TRSW_x, BIOZ_DSW_x, BIOZ_DRWSW_x. The input mux for the measurement path is controlled by the BIOZ_NCHAN_x and BIOZ_PCHAN_x. Table 10 shows the connections of the input mux with the related bit setting. The flexible design of the BIA channel allows different configurations of the measurement.

Table 10. TIA Connections in the BIA Channel

Bit Name	Setting	Connection
BIOZ_TSW_x	0001	IMPIP
	0010	IMPIN
	0100	EXCP
	1000	EXCN
BIOZ_TRSW_x	1	RCALN
BIOZ_RINT_SW_x, Bit 1	1	$R_{INT_SN}^1$
BIOZ_DSW_x	0001	IMPIP
	0010	IMPIN
	0100	EXCP
	1000	EXCN
BIOZ_DRWSW_x	1	RCALP
BIOZ_RINT_SW_x, Bit 0	1	$R_{INT_SP}^1$
BIOZ_PCHAN_x and BIOZ_NCHAN_x	00	TIA
	01	IMPIP and IMPIN
	10	RCALN and RCALP
	11	R_{INT}

¹ R_{INT_SN} and R_{INT_SP} refer to the two terminals of the internal resistor (R_{INT}).

The frequency of the generated sine wave is controlled by BIOZ_SINEFCW_x_x, whereas the amplitude of the sine wave is controlled by BIOZ_SINEAMPLITUDE_x. BIOZ_SINE_PHASE_OFFSET_x is used to control the sine wave phase.

Equation 2 and Equation 3 show how to set the voltage output (V_{OUT}) amplitude and sine wave frequency with these bits, respectively, as follows:

THEORY OF OPERATION

$$V_{OUT} = 0.8 \times \frac{BIOZ_SINEAMPLITUDE_x}{2^{11}} Vp - p \tag{2}$$

$$Frequency = \frac{32M \times BIOZ_SINEFCW_x}{2^{26}} Hz \tag{3}$$

BIOZ_DAC_GAIN_x and BIOZ_DAC_OFFSET_x are used to give more flexible control of the generated sine wave for different applications.

The TIA gain can be accessed through BIOZ_TIA_RGAIN_x.

After digitizing the measurement, the ADC output is sent to the datapath of the BIA channel, which includes filters, gain controls, and the DFT path (see the [Datapath](#) section for more information). The DFT result is I data and Q data of the received sine wave, and the data format is 18 bits.

When the chain turns on, the DFT path can wait before performing the DFT. The waiting time is controlled by BIOZ_ADC_CONV_DLY_x.

For accurate measurement, the chip must perform ratio measurement. That is, the chip needs to measure the known external resistor at the RCALP and RCALN pins, and then measure the unknown resistor. Use the ratio method to calculate the resistor under test.

FIFO

The FIFO is never written with partial packets of data. If there is not enough room for the data that is written to the FIFO for all enabled time slots and any selected status bytes, no data is written from any of the time slots during that period and the INT_FIFO_OFLOW status bit is set.

The order of samples written to the FIFO (if selected) is dark followed by lit data. [Table 11](#) shows the byte order for multibyte words.

Table 11. Byte Order for FIFO Writes

Size	Byte Order (After Shift)
8	[7:0]
16	[15:8], [7:0]
24	[23:16], [15:8], [7:0]
32	[31:24], [23:16], [15:8], [7:0]

The FIFO size is 640 bytes. When the FIFO is empty, a read operation returns 0xFF and the INT_FIFO_UFLOW status bit is set.

ECG Data Format

The data in the ECG is channel is 24-bit unsigned data with a status byte as a header. [Figure 33](#) shows the data in the ECG channel.

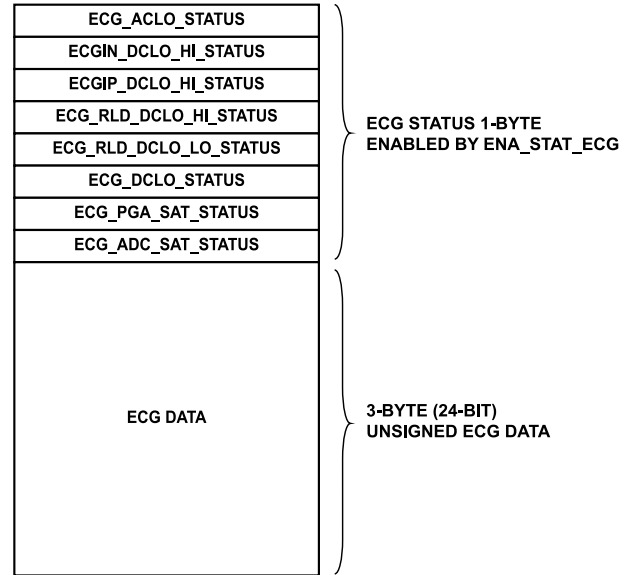

Figure 33. ECG Data Format

If ENA_STAT_ECG is set to 1, the ECG output data is a 4-byte structure, where the highest byte is the ECG related status information. If ENA_STAT_ECG is set to 0, the ECG output data is a 3-byte structure with only ECG channel output data.

PPG Data Format

At the end of each time slot, the selected data is written to the FIFO. The packet can include 0-, 8-, 16-, 24-, or 32-bit data for each of the dark data, signal data, or lit data values. The bit alignment of the data written to the FIFO is selectable with a shift of 0 bits to 31 bits, with saturation provided. Lower bits are ignored. The DARK_SIZE_x, LIT_SIZE_x and SIGNAL_SIZE_x bits select the number of bytes of each field to be written from 0 bytes to 4 bytes. When set to 0, no data is written for that data type. The DARK_SHIFT_x, LIT_SHIFT_x, and SIGNAL_SHIFT_x bits select the number bits to shift the output data to the right before writing the FIFO. If there are any significant bits at more significant bit positions than those selected, the data written to the FIFO is saturated.

The order of samples written to the FIFO (if selected) is signal data followed by dark data and then lit data. If both channels are enabled, all selected Channel 1 data values are written to the FIFO first, followed by the Channel 2 data.

For example, in modes that use dark data, the eight upper bits of the dark data can be stored with 24 appropriately selected bits from the signal data for each time slot. This method detects whether the ambient light is becoming large, while limiting the size of the amount of data transferred.

[PPG Data Format](#) shows the PPG data format in the FIFO.

THEORY OF OPERATION

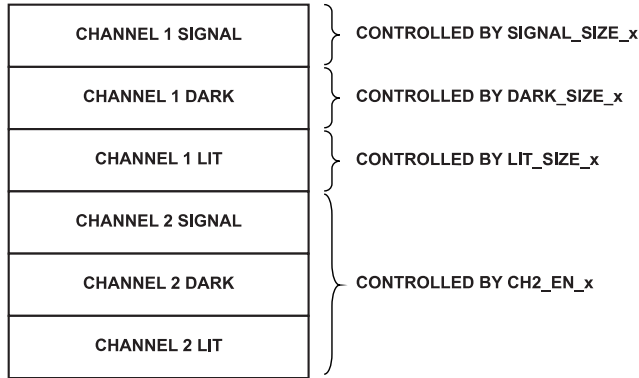

Figure 34. PPG Data Format

Figure 35. BIA Data Format

Data Arrangement in the FIFO

The data in the FIFO is arranged according to the enabled time slots and follow the same sequence.

For example, Figure 36 shows the data in the FIFO if one ECG time slot, three PPG time slots, and two BIA time slots are enabled.

BIA Data Format

The BIA data format is 3-byte I data followed by 3-byte Q data. Figure 35 shows the BIA data format in the FIFO.

Figure 36. Example of Data Arrangement in the FIFO (TSA Is Time Slot A, TSB Is Time Slot B, and TSC Is Time Slot C)

THEORY OF OPERATION

CLOCKING

Low Frequency Oscillator

A low frequency oscillator clocks the low speed state machine, which sets the time base used to control the sample timing, wake-up states, and overall operation. There are three options for low frequency oscillator generation. The first option is an internal 960 kHz oscillator. The second option is for the host to provide a low frequency oscillator externally. Finally, the low frequency oscillator can be generated by a divide by 32 of an external high frequency clock source at 32 MHz. When powering up the device, it is expected that the low frequency oscillator be enabled and left running continuously.

To operate with the on-chip low frequency oscillator, use the following writes. Set the `OSC_960K_EN` bit to 1 to turn on the internal oscillator. The internal 960 kHz clock frequency is set using the 10-bit `OSC_960K_FREQ_ADJ` bits.

If higher timing precision is required than can be provided by the on-chip low frequency oscillator, the low frequency oscillator can be driven directly from an external source provided on a GPIOx input. To enable an external low frequency clock, use the following writes. Enable one of the GPIOx inputs using the `GPIO_PIN_CFGx` bits. Next, use the `ALT_CLK_GPIO` bits to choose the enabled GPIOx input to be used for the external low frequency oscillator. Set the `ALT_CLOCKS` bits to 0x1 to select an external low frequency oscillator.

In a third method, an external 32 MHz clock is used for both the high frequency clock and to be divided down to generate the low frequency clock. To use this method, follow the previous instructions for an external low frequency clock but set the `ALT_CLOCKS` bits to 0x3, and a divide by 32 used to generate the low frequency clock so that a 1 MHz clock is generated from the external 32 MHz clock.

High Frequency Oscillator

A 32 MHz high frequency oscillator is generated internally or can be provided externally. This high frequency clock clocks the high speed state machine, which controls the AFE operations during the time slots, such as LED timing, integration times, and BIA excitation frequency.

The high frequency oscillator can be internally generated by setting the `ALT_CLOCKS` bits to 0x0 or 0x1. When selected, the internal 32 MHz oscillator is enabled automatically by the low speed state machine during the appropriate wake-up time or during the 32 MHz oscillator calibration routine.

The high frequency oscillator can also be driven from an external source. To provide an external 32 MHz high frequency oscillator, enable one of the GPIO inputs using the `GPIO_PIN_CFGx` bits. Then, use the `ALT_CLK_GPIO` bits to choose the enabled GPIOx input for the external high frequency oscillator. Finally, write 0x2 or

0x3 to the `ALT_CLOCKS` bits to select an external high frequency oscillator. Writing 0x2 provides only the high frequency oscillator from the external source, whereas writing 0x3 generates both the low frequency oscillator and high frequency oscillator from the external 32 MHz source. When using an external 32 MHz oscillator, it must be kept running continuously for proper device operation.

TIME STAMP OPERATION

The time stamp feature is useful for calibrating the low frequency oscillator as well as providing the host with timing information during time slot operation. Timestamping is supported by the use of any GPIO as a time stamp request input, the `CAPTURE_TIMESTAMP` bit to enable capture of the time stamp trigger, a time counter running in the low frequency oscillator domain, and two output registers. The output bits include `TIMESTAMP_COUNT_x`, which holds the number of low frequency oscillator cycles between time stamp triggers, and `TIMESTAMP_SLOT_DELTA`, which holds the number of low frequency oscillator cycles remaining to the next time slot start.

The setup for using the time stamp operation is as follows:

1. Set `OSC_CAL_ENABLE` = 1 to enable the oscillator calibration circuitry.
2. Configure a GPIO to support the time stamp input using the appropriate `GPIO_PIN_CFG_x` bits. Select the matching GPIOx to provide the time stamp using the `TIMESTAMP_GPIO` bits.
3. Configure the ADPD6000 for operation and enable the low frequency oscillator.
4. If the `TIMESTAMP_SLOT_DELTA` function is desired, start the time slot operation by placing the device in go mode using the `OP_MODE` bit (see [Table 12](#)). For low frequency oscillator calibration, it is only required that the low frequency oscillator is enabled. The device does not have to be in go mode for low frequency oscillator calibration.

Use the following procedure to capture the time stamp:

1. Set the `CAPTURE_TIMESTAMP` bit to 1 to enable the capture of the time stamp on the next rising edge of the selected GPIOx input.
2. The host provides the initial time stamp trigger on the selected GPIOx at an appropriate time.
3. The `CAPTURE_TIMESTAMP` bit is cleared when the timestamp signal is captured unless the `TIMESTAMP_ALWAYS_EN` bit is set, in which case, the capture of the time stamp is always enabled. Reenable the capture if necessary.
4. The host provides a subsequent time stamp trigger on the selected GPIO at an appropriate time.
5. The number of low frequency oscillator cycles that occurred between time stamp triggers can be read from the `TIMESTAMP_COUNT_x` bits.

The host must continue to handle the FIFO data normally during time stamp processing.

THEORY OF OPERATION

If using a dedicated pin for a time stamp that does not have transitions other than the time stamp, set the `TIMESTAMP_ALWAYS_EN` bit to avoid automatic clearing of the `CAPTURE_TIME_STAMP` bit. This setting removes the need to enable the time stamp capture each time.

The host can also use `TIMESTAMP_SLOT_DELTA` to determine when the next time slot occurs. `TIMESTAMP_SLOT_DELTA` can determine the arrival time of the samples currently in the FIFO.

The time stamp trigger is edge sensitive and can be set to either trigger on the rising edge (default) or falling edge using `TIMESTAMP_INV`.

Low Frequency Oscillator Calibration

The time stamp circuitry can calibrate the 960 kHz low frequency oscillator circuit by adjusting the frequency to match the timing of the time stamp triggers. Simply compare the `TIMESTAMP_COUNT_x` value in low frequency oscillator cycles to the actual time stamp trigger period and adjust the `OSC_960K_FREQ_ADJ` value accordingly.

High Frequency Oscillator Calibration

The high frequency oscillator is calibrated by comparing multiples of its cycles with multiple cycles of the low frequency oscillator, which is calibrated to the system time. Calibration of the low frequency oscillator precedes calibration of the high frequency oscillator. The method for calibrating the high frequency oscillator is as follows:

1. Set `OSC_CAL_ENABLE` = 1 to enable the oscillator calibration circuitry.
2. Write 1 to the `OSC_32M_CAL_START` bit.
3. The ADPD6000 automatically powers up the high frequency oscillator.
4. The device automatically waits for the high frequency oscillator to be stable.
5. An internal counter automatically counts the number of 32 MHz high frequency oscillations that occur during 128 cycles of the 960 kHz low frequency oscillator.
6. The `OSC_32M_CAL_COUNT` bits update with the final count.
7. The 32 MHz oscillator automatically powers down following calibration unless time slots are active.
8. The device resets the `OSC_32M_CAL_START` bit indicating the count has updated.

The `OSC_32M_FREQ_ADJ` bits adjust the frequency of the 32 MHz oscillator to the desired frequency. When using an external low frequency oscillator, the 32 MHz oscillator calibration is performed with respect to the externally provided low frequency oscillator.

When the calibrations of the low frequency and high frequency oscillators are complete, set `CLK_CAL_ENA` = 0 to disable the clocking of the oscillator calibration circuitry to reduce the power

consumption. `CLK_CAL_ENA` defaults to 0 so that the calibration circuitry is disabled by default.

EXECUTION MODES

A state machine in the low frequency oscillator clock domain controls sleep times, wake-up cycles, and the start of time slot operations. The low frequency oscillator serves as the time base for all time slot operations, controls the sample rates, and clocks the low frequency state machine. This state machine controls all operations and is controlled by the `OP_MODE` bit.

Table 12. *OP_MODE* Bit Setting Descriptions

OP_MODE Setting	Mode	Description
0	Standby	All operations stopped. Time slot actions reset. Low power standby state.
1	Go	Transitioning to this state from standby mode starts time slot operation.

At power-up and following any subsequent reset operations, the ADPD6000 is in standby mode. The user can write 0 to the `OP_MODE` bit to immediately stop operations and return to standby mode.

The time slots are enabled by the `ECG_TIMESLOT_EN`, `PPG_TIMESLOT_EN`, and `BIOZ_TIMESLOT_EN` bits in the `OP_MODE` register (see Table 1). Set `ECG_TIMESLOT_EN` to 1 enable the ECG time slot. Set the `BIOZ_TIMESLOT_EN` value and `PPG_TIMESLOT_EN` value to enable the corresponding BIOZ time slots and PPG time slots, respectively.

After enabling the desired time slots, set the `OP_MODE` bit to 1 to start the chip operation.

Register writes that affect operating modes cannot occur during go mode. The user must enter standby mode before changing the control registers. Standby mode resets the digital portion of the ADC, all of the pulse generators, and the state machine.

When `OP_MODE` is set to 1, the device immediately starts the first wake-up sequence and time slot operations unless using an external synchronization trigger. If using an external synchronization trigger, the device enters the sleep state before the first wake-up and time slot regions begin.

HOST INTERFACE

The ADPD6000 uses an SPI to communicate with other devices. The device also provides numerous FIFO, error, and threshold status bits, each of which can be provided by an interrupt function from a GPIO, read from status registers, or appended as optional status bytes at the end of a FIFO packet.

Interrupt Status Bits

FIFO Threshold Interrupt

The FIFO threshold interrupt status bit, `INT_FIFO_TH`, is set when the number of bytes in the FIFO exceeds the value stored in the

THEORY OF OPERATION

FIFO_TH register. The INT_FIFO_TH bit is cleared automatically when a FIFO read reduces the number of bytes below the value in the FIFO_TH register, which allows the user to set an appropriate data size for their host needs.

The INT_FIFO_TH bit does not trigger if the FIFO byte count exceeds the threshold in the middle of any write of complete data. Instead, the INT_FIFO_TH bit is set at the next write to the FIFO. For example, if only PPG TSA is running, it only writes 4-byte lit data to the FIFO. [Figure 37](#) shows the data in the FIFO.

Figure 37. FIFO Threshold Interrupt Example

If the threshold is set as 4, the interrupt triggers at the beginning of the second TSA data write to the FIFO. If the threshold is set as 5, 6, or 7, the INT_FIFO_TH bit does not trigger until the write of the third TSA data. This method can help prevent any partial data read from the FIFO.

Clearing Interrupt Status Bits

All status bits are set regardless of whether the status bit is routed to one of the interrupt outputs, Interrupt X or Interrupt Y. The status bits are independent of the interrupt enable bits. The status bits are always set by the corresponding event. The interrupt bits stay set until they are either manually or automatically cleared.

The user can manually clear a given interrupt by writing a 1 to the matching interrupt status bit. In addition, the data interrupt status bits can be configured to clear automatically. When the INT_ACLEAR_FIFO bit is set, the appropriate interrupt status bit is automatically cleared when any matching FIFO register is read. Automatic clearing of the interrupt status bits removes the need to manually clear these interrupts.

Optional Status Bytes

There is an option to append each data packet with status bits. This option is useful for hosts that cannot spare an interrupt channel to service. The status bytes can each be individually selected in the FIFO_STATUS_BYTES register. Each bit in the FIFO_STATUS_BYTES register enables a status byte that is appended to the data packet in the FIFO. If any bit in the FIFO_STATUS_BYTES register is set to 1, the byte that is appended to the data packet contains the status bits.

The 4-bit sequence number cycles from 0 to 15 and is incremented with a wraparound every time the time slot sequence completes. This sequence number can also be made available bitwise on the GPIOx pins.

Interrupt Outputs, Interrupt X and Interrupt Y

The ADPD6000 supports two separate interrupt outputs, Interrupt X and Interrupt Y. Each interrupt has the option to be driven to any of the four GPIOx pins. The two different interrupt outputs can be generated for a host processor if desired. For example, the FIFO threshold interrupt, INT_FIFO_TH, can be routed to Interrupt X and used to drive the direct memory access (DMA) channel of the host, while the INT_FIFO_OFLOW and INT_FIFO_UFLOW interrupts can be routed to Interrupt Y and used to drive an additional host interrupt pin.

For each interrupt, there is an associated Interrupt X and Interrupt Y enable bit. See [Table 1](#) for a full list of available interrupts that can be brought out on Interrupt X and Interrupt Y. The logic for the Interrupt X and Interrupt Y function is a logic AND of the status bit with its matching enable bit. All enabled status bits are then logically OR'ed to create the interrupt function. The enable bits do not affect the status bits.

General-Purpose I/Os

The ADPD6000 provides three general-purpose I/O pins: GPIO0, GPIO1, and GPIO2. These GPIOs can be used as previously described in the [Interrupt Outputs, Interrupt X and Interrupt Y](#) section for interrupt outputs or for providing external clock signals to the device. The GPIOs can also be used for many different control signals, as synchronization controls to external devices, as well as test signals that are useful during system debugging. All of the available signals that can be brought out on a GPIOx pin are listed in [Table 1](#).

IOVDD Supply Voltage Consideration

The ADPD6000 can operate with IOVDD as low as 1.7 V and as high as 3.6 V. LOW_IOVDD_EN in Register 0x0057 is set to 0x1 for IOVDD lower than 3 V. 0x1 is the default value for this bit because the typical IOVDD value is 1.8 V.

If 3 V or higher is supplied for IOVDD, the LOW_IOVDD_EN bit must be set to 0x0 for proper operation.

SPI

The ADPD6000 contains an SPI port that operates synchronously with its input clocks.

The ADPD6000 has an internal power-on reset circuit that sets the device into a known idle state during the initial power-up. After the power-on reset is released, approximately 2 μ s to 6 μ s after the DVDD supply is active, there is an initialization state that sets the register default values. This initialization state lasts approximately 15 μ s to 20 μ s. The device can then be read and written through the SPI.

The registers are accessed using addresses within a 15-bit address space. Each address references a 15-bit register with one address reserved for the FIFO read accesses. For SPIs, reads and writes

THEORY OF OPERATION

auto-increment to the next register if additional words are accessed as part of the same access sequence. This automatic address increment occurs for all addresses except the FIFO address, one less than the FIFO address and the last used address, which is 0x351. Reads from the FIFO address continue to access the next byte from the FIFO.

SPI Operations

The SPI single register write operation is shown in Figure 38. The first two bytes contain the 15-bit register address and specify that a write is requested. The remaining two bytes are the 16 data bits to write to the register. The register write occurs only when all 16 bits are shifted in prior to deassertion of the \overline{CS} signal.

In addition, multiple registers can be written if additional 16-bit data is shifted in before deassertion of the \overline{CS} signal. The register address automatically increments to the next register after each 16 bits of data.

The SPI single register read operation is shown in Figure 39. The first two bytes contain the 15-bit register address and specify that a read is requested. Register bits are shifted out starting with the MSB. In addition, multiple registers can be read if additional 16-bit data is shifted out prior to deassertion of the \overline{CS} signal.

It is recommended that reading from the FIFO is performed byte wise. There is no requirement to read multiples of 16 bits.

Figure 38. SPI Write Operation

Figure 39. SPI Read Operation

APPLICATIONS INFORMATION

OPTICAL PATH

Digital Integration Mode

The ADPD6000 supports a digital integration mode in the optical path to accommodate sensors that require longer pulses. Digital integration mode allows the system to use a larger LED duty cycle, which may result in the highest achievable levels of SNR.

Figure 40. Signal Path for Digital Integration Mode

In digital integration mode, the integrator is configured as a buffer, resulting in the signal path shown in Figure 40. Digital integration regions are configured by the user and separated into lit and dark regions. The LED is pulsed in the lit region, and the LED is off in the dark region. ADC samples are taken at 1 μ s intervals within the lit and dark regions and are then digitally integrated. The integration of the ADC samples from the dark region is subtracted from the integration of the ADC samples from the lit region and the result is written into the relevant FIFO. Both signal and dark values can be written to the FIFO.

The ADPD6000 supports one-region and two-region digital integration modes. In one-region digital integration mode, an equal number of dark and lit samples are taken where all of the dark samples are taken in the dark region just prior to the lit region. One-region digital integration mode is shown in the timing diagram in Figure 41.

In two-region digital integration mode, an equal number of dark and lit samples are taken. However, the dark region is split such that half of the samples are taken in the dark region prior to the lit region, and the other half is taken in the dark region following the lit region. The two-region digital integration mode results in higher ambient light rejection than the one-region digital integration mode in situations with a varying ambient light level. A timing diagram for two-region digital integration mode is shown in Figure 42.

The signal data for one-region digital integration mode that reads from the FIFO follows Equation 4:

$$Signal = (I_{PD} \times R_{TIA} \times TIA_Config \times Buf_Gain \times NUM_INT_x \times NUM_REPEAT_x) / (146\mu V / LSB) \quad (4)$$

where:

I_{PD} is the PD current.

TIA_Config is the TIA configuration.

Buf_Gain is the buffer gain.

The signal data for two-region digital integration mode that reads from the FIFO follows Equation 5:

$$Signal = ((I_{PD} \times R_{TIA} \times TIA_Config \times Buf_Gain \times NUM_INT_x \times NUM_REPEAT_x) / (146\mu V / LSB)) \times 2 \quad (5)$$

The $AFE_PATH_CFG_x$, $CHx_TRIM_INT_x$, and $CHx_TRIM_INT_CAP_x$ bits need to follow a certain combination in digital integration mode (both one-region mode and two-region mode). Table 13 shows the recommended settings of these bits. The TIA gain setting is independent of these settings.

Table 13. Bit Settings for AFE Path in Digital Integration Mode

Bit Name	Recommended Setting
$AFE_INT_C_BUF_x$	0x0
$AFE_PATH_CFG_x$	0x28
$CHx_TRIM_INT_x$	0x3
$CHx_TRIM_INT_CAP_x$	0x1

The result of the configurations of the bits in Table 13 is 1 \times TIA configuration with buffer gain = 2.

Table 14 shows the relevant register settings for the digital integration modes of operation. The MIN_PERIOD_x bits must be set manually with the proper period because the minimum period is not automatically calculated in digital integration mode.

The recommended MIN_PERIOD_x setting for one-region digital integration mode is as follows:

$$MIN_PERIOD_x = NUM_INT_x \times 2 + (2 + t_D) \times 2$$

The recommended MIN_PERIOD_x setting for two-region digital integration mode is as follows:

$$MIN_PERIOD_x = NUM_INT_x \times 4 + t_D \times 2 + 6\mu s$$

The t_D value is the response time of the optical device. The 6 μ s time is essential for the ambient fine loop update.

Table 14. Relevant Settings for Digital Integration Modes

Group	Time Slot A Register Address	Bit Field Name	Description
Signal Path Setup	0x0120, Bits[13:11]	SAMPLE_TYPE_x	Set to 0x2 for one-region digital integration mode. Set to 0x3 for two-region digital integration mode.
	0x0121, Bits[6:0]	AFE_PATH_CFG_x	Set to 0x28 for TIA, buffer, and ADC. Use 1x TIA configuration.
	0x0122, Bits[7:0]	INPxx_x	Enable desired inputs.
	0x0123, Bits[14:12]	PRECON_x	Set to 0x5 to precondition anode of photodiode to TIA_VREF.
	0x0123, Bits[7:6], Bits[1:0]	VCx_SELECT_x	Set to 0x2 to set ~215 mV reverse bias across photodiode.
	0x0124, Bits[5:0]	TIA_GAIN_CHx_x	Select TIA gain.
	0x0124, Bits[9:8]	AFE_TRIM_VREF_x	Set to 0x2 to set TIA_VREF = 0.8855 V.
	0x0124, Bits[12:11], Bits[14:13] 0x125, Bits[13:12]	CH1_TRIM_INT_x CH1_TRIM_INT_CAP_x	Set to 0x3 to set buffer gain = 2. Set to 0x1 to 12.6 pF
Timing	0x012A, Bits[15:8]	NUM_INT_x	Set to the number of desired ADC conversions in the dark and lit regions.
	0x012A, Bits[7:0]	NUM_REPEAT_x	Number of sequence repeats.
	0x012B, Bits[9:0]	MIN_PERIOD_x	Set the period. Automatic period calculation is not supported in digital integration mode.
	0x0138, Bits[8:0]	LIT_OFFSET_x	Set to the time of the first ADC conversion in the lit region.
	0x0139, Bits[6:0]	DARK1_OFFSET_x	Set to the time of the first ADC conversion in the Dark 1 region.
	0x0139, Bits[15:7]	DARK2_OFFSET_x	Set to the time of the first ADC conversion in the Dark 2 region. Only used in two-region digital integration mode.
LED Settings	0x0129, Bits[1:0]	LED_MODEx_x	Select LED mode.
	0x0128, Bit 15 and Bit 7	LED_DRIVESIDEx_x	Select LED for time slot used.
	0x0128, Bits[14:8], Bits[6:0]	LED_CURRENTx_x	Set LED current for selected LED.
	0x012C, Bits[7:0]	LED_OFFSET_x	Sets start time of first LED pulse in 1 μ s increments.
	0x012C, Bits[15:8]	LED_WIDTH_x	Sets width of LED pulse in 1 μ s increments.

APPLICATIONS INFORMATION

Timing Recommendations for Digital Integration Mode

When setting the timing for digital integration mode, it is important to place the ADC samples such that the signal being sampled is given time to settle prior to the sample being taken. Settling time of the input signal is affected by photodiode capacitance and TIA settling time.

If automatic ambient light rejection is turned on (AMBIENT_CANCELLATION_x is set to either 1 or 2), some time is needed at the beginning of each time slot to enable the ambient rejection loop. The start-up time of this loop is 18 μ s, and the working time of this loop is 30 μ s.

The TIA_SAT_DET internal block must be turned on to speed up the TIA settling. Speeding up the TIA settling can help the TIA enter a normal working state quickly to make the automatic ambient rejection loop more accurate.

After the ambient loop completes, the first ADC sample of dark data can be enabled. The DARK1_OFFSET_x setting must be equal or larger than the ambient loop working time (48 μ s).

Figure 43 shows an example of the proper placement of the ADC sampling edges.

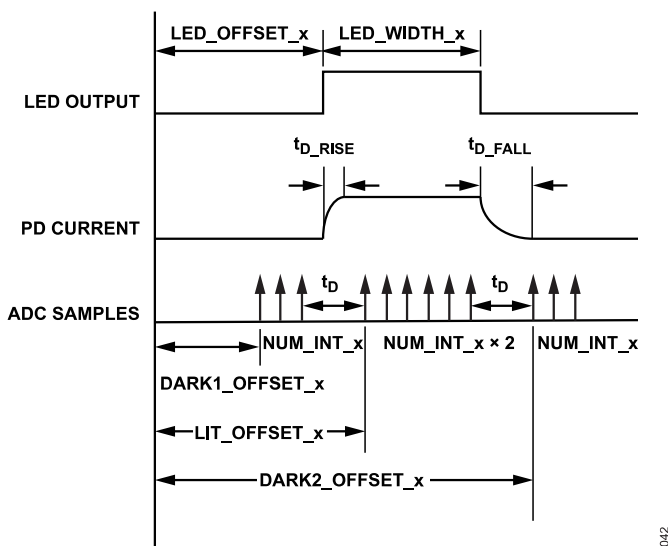

Figure 43. Proper Placement of ADC Sampling Edges in Digital Integration Mode

The recommended DARK1_OFFSET_x setting after the automatic ambient loop completes is 48 μ s, or 10 μ s if automatic ambient rejection is not turned on.

As shown in Figure 43, different optical devices, including the LED and photodiode, have different response times. t_{D_RISE} is the rising time of the photodiode current, and t_{D_FALL} is the falling time of the photodiode current. t_D is either t_{D_RISE} or t_{D_FALL} , depending on which one is bigger.

See the following equations:

$$LED_OFFSET_x = DARK1_OFFSET_x + (NUM_INT_x + t_D - t_{D_RISE}) \quad (6)$$

$$LIT_OFFSET_x = LED_OFFSET_x + t_{D_RISE} \quad (7)$$

$$DARK2_OFFSET_x = LED_OFFSET_x + LED_WIDTH_x + t_D \quad (8)$$

These values must be characterized in the final application. These settings only apply to two-region digital integration mode.

Table 15. Empirical Values for Two-Region Digital Integration Mode

Optical Device	Green (μ s)	Red (μ s)	Infrared (μ s)
LED_WIDTH_x	24	24	36
PERIOD_x	58	60	138
NUM_INT_x	10	9	13
LED_OFFSET_x	60	59	91
LIT_OFFSET_x	64	65	101
DARK1_OFFSET_x	48	48	48
DARK2_OFFSET_x	90	91	167
t_{D_RISE}	4	6	10
t_{D_FALL}	6	8	40

Optimizing Sampling Sequence

If the empirical value is not appropriate for the measurement, optimize the sampling sequence.

See the following reference method for sweeping the curve (this example is based on TSA Channel 1 in a dark environment):

- Enable the following settings:
 - ▶ One-region digital integration mode
 - ▶ 1x TIA configuration
 - ▶ AFE_TRIM_VREF_A = 3
 - ▶ AMBIENT_CANCELLATION_A = 0
 - ▶ NUM_INT_A = 1
 - ▶ NUM_REPEAT_A = 1
 - ▶ DARK1_OFFSET_A = 10
 - ▶ LED_OFFSET_A = 20
 - ▶ LED_WIDTH_A = 80
 - ▶ LIT_OFFSET_A = 130
 - ▶ MIN_PERIOD_A = 160
- Power on the optical devices and enable TSA Channel 1.
- Collect about 100 lit data values (remove the first 10 data values) and calculate the mean value.
- Sweep the LIT_OFFSET_A bit from 130 to 10 and reproduce the result from Step 3.
- Plot the mean value of the lit data and LIT_OFFSET_A. The response time of the optical device (for example, CT_DBLP3112) is shown in Figure 44.

APPLICATIONS INFORMATION

When collecting the lit data with the LIT_OFFSET_A bit changing, the data is lower than 16384 (unsaturated).

Figure 44. Timing of CT_DBLP3112 (Green LED)

Figure 45. System Overview of ECG Circuit Showing ECG Channel Protection and External Components Requirements

ECG PATH

Figure 45 shows a typical connection diagram for the three-electrode ECG application. Figure 45 captures the external components required around ADPD6000, including current limitation resistors for the ECG channel. These component values were designed by users considering the maximum current of every channel. For example, it is suggested to use 51 kΩ, 51 kΩ, and 330 kΩ on the ECGIP, ECGIN, and RLD channels, respectively, for reference.

The signal data for ECG measurement that is read from FIFO follows Equation 9:

$$Signal = \frac{V_{IN}(V)}{Resolution} + 8,388,608 \text{ (LSB)} \quad (9)$$

Note that 8,388,608 is the center code of the ADC.

Table 16 shows the relevant register settings for the basic ECG measurement.

Table 16. Relevant Settings for ECG Measurement

Group	Register Address	Bit Field Name	Description
ECG_ANA_CTRL	0x0100, Bit 10	ECG_INP_CONNECT	ECG input connection. Set 1 to connect the ECG inputs.
	0x0100, Bit 8	ECG_CHAN_RESOLUTION	Set to 0 for 286 nV/LSB, and set to 1 for 572 nV/LSB.
	0x0100, Bits[5:4]	ECG_RLD_OUT_SEL	Set to 0x3 to set regulated common-mode input.
	0x0100, Bit 3	ECG_RLD_SAT_EN	Set to 1 to enable DCLO for RLD.
	0x0100, Bits[2:1]	ECG_RLD_SAT_THRESHOLD	Select the DCLO threshold for RLD.
	0x0100, Bit 0	ECG_RLD_EN	Set to 1 to enable RLD.
ECG_LEADOFF_CTRL	0x0101, Bit 15	ECG_ACLO_EN	Set to 1 to enable the ACLO detector for the ECG inputs.
	0x0101, Bits[14:12]	ECG_ACLO_MAG	Select the ACLO excite current magnitude.
	0x0101, Bits[11:9]	ECG_ACLO_THRESHOLD	Select ACLO threshold for the ECG inputs.
	0x0101, Bit 8	ECG_DCLO_EN	Set to 1 to enable the DCLO detector for the ECG inputs.
	0x0101, Bits[7:4]	ECG_DCLO_MAG	Select the DCLO excite current magnitude.
	0x0101, Bit 3	ECG_DCLO_POLARITY_IN	Select DCLO output current polarity at ECGIN.
	0x0101, Bit 2	ECG_DCLO_POLARITY_IP	Select DCLO output current polarity at ECGIP.
ECG_DIG_CTRL	0x0102, Bits[8:3]	ECG_OVERSAMPLE_RATIO	For ECG only mode, keep the default value. For multimodal, refer to the register description.
	0x0102, Bits[2:0]	ECG_ODR_SEL	Select the ECG ODR.

APPLICATIONS INFORMATION

Lead Off

DCLO detection uses the ECG_STATUS register to identify the lead connection status. Figure 46 shows an example of DCLO detection. In the case, R1, R2, and R3 are the contact impedances at ECGIP, ECGIN, and RLD, respectively.

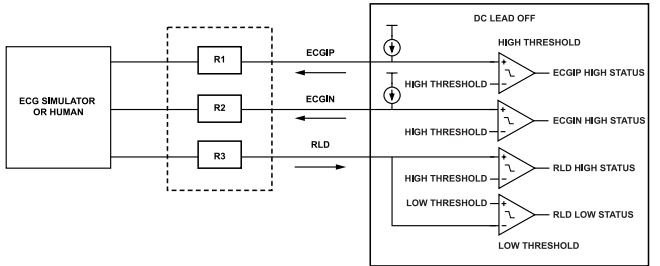

Figure 46. DCLO Detection Example

When using source current at ECGIP and ECGIN, the dc excitation current setting (ECG_DCLO_MAG) follows Equation 10:

$$\text{If } R1 = R2 = R3 = 3R,$$

$$\left(\frac{\text{DCLO Current Magnitude} > \text{High Threshold Voltage}}{3R} \right) \tag{10}$$

Generally, the DCLO current magnitude setting is rounded up to nearest register value.

Table 17 is the ECG DCLO status truth table.

ACLO threshold selection depends on the particular cable, electrode, or protection scheme because these parameters are typically unique for the specific use case. Identifying the appropriate threshold can start with a high threshold and ratchet it down until a lead off is detected, then increase the threshold by some safety margin.

Table 18 shows the low threshold of electrode difference capacitance for ACLO detection.

Table 17. ECG DCLO Status Truth Table

Status	ECGIN_DCLO_HI_STATUS	ECGIP_DCLO_HI_STATUS	ECG_DCLO_STATUS
All Leads Failed	1	1	1
No Lead Failed	0	0	0
RLD Failed	1	1	1
ECGIN Right Arm (RA) Failed	0	1	1
ECGIP Left Arm (LA) Failed	1	0	1

APPLICATIONS INFORMATION

BIA PATH

The BIA path in the ADPD6000 can be used to perform 4-wire impedance measurement on the body. This approach uses a high precision, ac voltage source to excite a sensor with a known ac voltage (VAC). To calculate the impedance, measure the current (I) that flows from the unknown impedance ($Z_{UNKNOWN}$) and the voltage across the unknown impedance ($V_{Z_UNKNOWN}$). Calculate the impedance by using the following equation:

$$|Z_{UNKNOWN}| = \frac{V_{Z_UNKNOWN}}{I} \quad (11)$$

In real-world applications, medical devices must conform to the IEC 60601 standard. This standard limits the amount of dc and ac voltage that can be applied to the human body.

In Figure 47, there are discrete isolation capacitors (C_{ISO1} , C_{ISO2} , C_{ISO3} , and C_{ISO4}) that ensure no dc voltage occurs across the body. R_{LIMIT} limits the current provided to the sensor to conform to the IEC 60601 standard.

$R_{CONTACT}$ represents the resistances of the electrodes connecting to the unknown impedance.

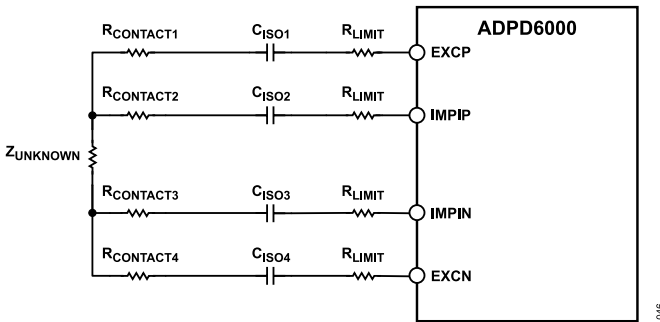

Figure 47. BIA Path Diagram

As shown in Figure 47, a 4-wire bioimpedance solution requires a precision ac voltage source, a high precision current meter, and a precision differential voltage meter.

The ADPD6000 uses a high speed DAC and waveform generator to generate the precision ac voltage. The device uses a high speed, high precision TIA for converting current from the sensor into a voltage measured by the ADC. The TIA channel measures the response current.

The ADC converts the current measurement with a 1 MSPS speed. A DFT is performed on the data. The DFT is implemented on the ADPD6000. The number of DFT points is configurable up to 8192. The ADPD6000 calculates the real and imaginary parts, and

the host microcontroller calculates the unknown impedance of the sensor.

There are a number of discrete components needed in the system to guarantee safety and accuracy.

To conform to IEC 60601 standards, limit the amount of ac current entering the human body. The maximum allowable ac current is 500 μ A at 50 kHz and 600 μ A at 60 kHz. When calculating the R_{LIMIT} resistor value, the maximum output voltage from the ADPD6000 is 0.8 V p-p (0.2828 V rms). Set the maximum allowable ac current to 80% of maximum, or 400 μ A rms. The following equation is the result of these values:

$$R_{LIMIT} = \frac{0.2828V_{rms}}{400\mu A} = 707\Omega \quad (12)$$

As such, a ~ 1 k Ω R_{LIMIT} is selected and connected to the EXCP pin on the ADPD6000. This calculation ignores C_{ISOx} because of its small size.

To conform to IEC 60601 standards, a 10 μ A maximum dc current is allowed to enter the human body. In this application, the dc current is guaranteed to be zero due to the addition of isolation capacitors. A value of 0.47 μ F is selected for the isolation capacitors because 0.47 μ F is a sufficiently large capacitance that is also available in small packages suitable for wearable electronics.

The ADPD6000 runs the BIA time slot and fills the FIFO with the DFT real and imaginary results for both the voltage and current measurements (four data points in total). The host microcontroller reads the data FIFO and uses the real and imaginary DFT results to calculate the unknown impedance. Calculate the impedance of the sensor by using the following equations:

$$\text{Voltage Measurement Magnitude} = \sqrt{r^2 + i^2} \quad (13)$$

$$\text{Voltage Measurement Phase} = \tan^{-1} \frac{i}{r} \quad (14)$$

To calculate the impedance, use Ohm's law by dividing the voltage magnitude by the current magnitude. Convert the current measurement value into a voltage using R_{TIA} . This gain must be taken into account. Therefore, the equation to determine the unknown impedance is as follows:

$$|Z_{UNKNOWN}| = \frac{\text{Voltage Magnitude}}{\text{Current Magnitude}} \times R_{TIA} \quad (15)$$

MULTIMODAL

Figure 48 shows the basic design reference schematic for PPG, ECG, and BIA multimodal applications.

APPLICATIONS INFORMATION

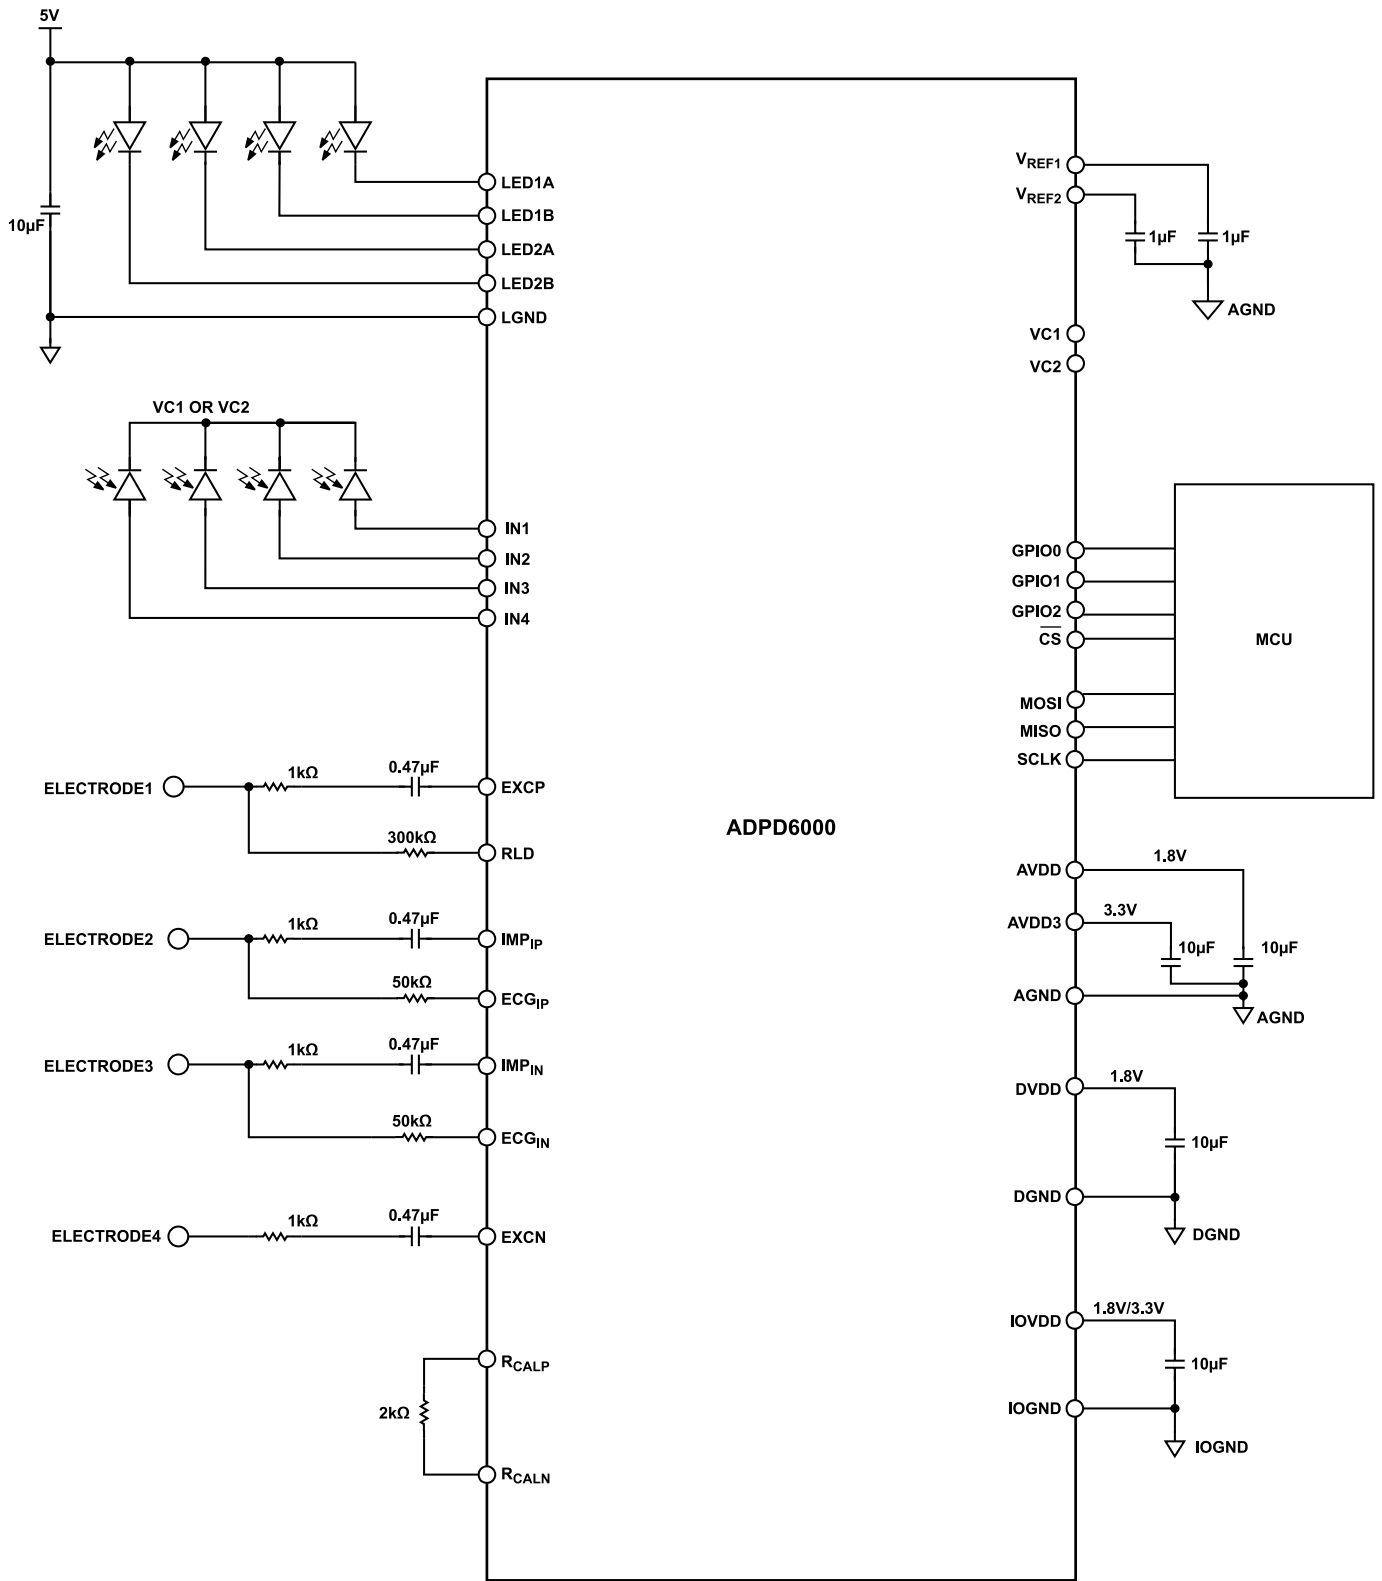

Figure 48. Multimodal Application Reference Schematic

APPLICATIONS INFORMATION

Recommended Configurations for Multimodal Measurement

The following is one of the recommended configurations for BIOZ, ECG, and PPG operation. The data pattern in the FIFO is ECG × 5 + PPG_A + PPG_B + BIOZ_A + BIOZ_B + BIOZ_C + BIOZ_D = 52 bytes.

```
#System configuration
0006 0034 # FIFO Interrupt Generation Threshold 52bytes
000F 0002 # Enable Low Frequency Oscillator 960KHz
0009 00B2 # High frequency oscillator Frequency control

```

Power-Up Sequencing

Note that the power supplies need to be on and off simultaneously.

FIFO Data Structure

Table 19 shows the data structure in the FIFO for the recommended multimodal measurement configuration. There are 52 bytes for every data pattern.

Table 19. Data Structure in FIFO

Byte Order in FIFO	Description
Byte 0 to Byte 19	ECG data: 20 bytes
Byte 20 to Byte 23	PPG_A data: 4 bytes
Byte 24 to Byte 27	PPG_B data: 4 bytes
Byte 28 to Byte 33	BIOZ_A data: 6 bytes
Byte 34 to Byte 39	BIOZ_B data: 6 bytes
Byte 40 to Byte 45	BIOZ_C data: 6 bytes
Byte 46 to Byte 51	BIOZ_D data: 6 bytes

DESIGN GUIDE

The ADPD6000 is a multimodal, vital sign monitoring AFE. The performance of the device can be adversely impacted by the PCB layout, especially for the analog input interfaces.

Power Rails

For the power supply, decouple the AVDD, AVDD3, DVDD, and IOVDD pins with a 0.1 μ F or larger ceramic chip capacitor to the PCB ground plane placed near the power pins. It is recommended

that all decoupling capacitors use individual vias to the PCB ground plane to avoid mutual impedance coupling between decoupled supplies when sharing vias.

Optical Channel

For the PPG channel, decouple the VREF1 pin and VREF2 pin to the PCB ground plane with a 1.0 μ F ceramic capacitor. The voltage on the VREF1 pin and VREF2 pin is nominally 1.2 V. Therefore, a 6.3 V rated ceramic capacitor is adequate for this purpose. The most critical aspect of the PCB layout of the ADPD6000 is the handling of the IN1, IN2, IN3, and IN4 nodes. Because photodiode input is sensitive to noise, and any parasitic capacitive coupling to the pin can result in additional noise, it is recommended that the photodiode input trace in the layout be as short as possible and fully guarded by the ground plane.

For example, as a 6-layer stack design, the chip is placed in the top layer with optical components in the bottom layer. Therefore, it is recommended that the IN1, IN2, IN3, and IN4 trace length in the top is short to avoid parasitic effects. In the bottom layer, the IN1, IN2, IN3, and IN4 traces and the photodiode anode are fully guarded with the ground shape and trace. VC1, VC2, and the photodiode cathode are also guarded with the ground plane. Layer 5 is filled with a ground plane for reference. Keep the analog input signals away from other digital or noisy signals.

ECG Channel

For the ECG channel, both traces of ECGIP and ECGIN must match to achieve high CMRR performance. Use a differential pair layout for ECGIP and ECGIN and shorten the length of the traces.

BIA Channel

For the BIA channel, minimize the length of the PCB trace for RCALP and RCALN because the RCALP and RCALN value is critical for the BIOZ measurement accuracy. The resistance of the PCB trace is designed to guarantee that the accuracy of the RCALP and RCALN resistance is 0.1%, even including the PCB wire resistance.

REGISTER DETAILS

Table 21. Register Details

Reg	Name	Bits	Bit Name	Description	Reset	Access
0x0000	FIFO_STATUS	15	CLEAR_FIFO	Clear FIFO. Write a 1 to empty the FIFO while not operating. This resets FIFO_BYTE_COUNT and also clears the INT_FIFO_OFLOW, INT_FIFO_UFLOW, and INT_FIFO_TH status bits. After the FIFO is cleared, CLEAR_FIFO must be set to 0 for the FIFO function.	0x0	R0W
		14	INT_FIFO_UFLOW	FIFO underflow error. This bit is set when the FIFO is read while empty. Write 1 to this bit to clear the interrupt. This bit is also cleared if the FIFO is cleared using the CLEAR_FIFO bit.	0x0	R/W1C
		13	INT_FIFO_OFLOW	FIFO overflow error. This bit is set when data is not written to the FIFO due to a lack of space. Write 1 to this bit to clear the interrupt. This bit is also cleared if the FIFO is cleared with the CLEAR_FIFO bit.	0x0	R/W1C
		12	INT_FIFO_TH	FIFO_TH interrupt status. This bit is set during a FIFO write when the number of bytes in the FIFO exceed the FIFO_TH register value. Write 1 to this bit to clear this interrupt. This bit can also be automatically cleared when the FIFO data register is read if the INT_ACLEAR_FIFO bit is set.	0x0	R/W1C
		11	FIFO_INIT_DONE_STATUS	FIFO initialization process is finished. Note that this bit is a status bit and is not sent to the interrupt. This bit is set after the FIFO self initialization process.	0x0	R
		[10:0]	FIFO_BYTE_COUNT	Number of bytes in FIFO. This field indicates the number of bytes in the FIFO.	0x0	R
0x0004	ECG_STATUS	[15:8]	RESERVED	Reserved.	0x0	R
		7	ECG_ACLO_STATUS	ECG ACLO status bit. Write 1 to this bit to clear this status.	0x1	R/W1C
		6	ECGIN_DCLO_HI_STATUS	ECGIN DCLO HI status bit. Write 1 to this bit to clear this status.	0x1	R/W1C
		5	ECGIP_DCLO_HI_STATUS	ECGIP DCLO HI status bit. Write 1 to this bit to clear this status.	0x1	R/W1C
		4	ECG_RLD_DCLO_HI_STATUS	ECG RLD DCLO HI status bit. Write 1 to this bit to clear this status.	0x1	R/W1C
		3	ECG_RLD_DCLO_LO_STATUS	ECG RLD DCLO LO status bit. Write 1 to this bit to clear this status.	0x1	R/W1C
		2	ECG_DCLO_STATUS	ECG DCLO status bit. Write 1 to this bit to clear this status.	0x1	R/W1C
		1	ECG_PGA_SAT_STATUS	ECG PGA saturation status bit. Write 1 to this bit to clear this status.	0x0	R/W1C
0	ECG_ADC_SAT_STATUS	ECG ADC saturation status bit. Write 1 to this bit to clear this status.	0x0	R/W1C		
0x0005	GLOBAL_STATUS	[15:1]	RESERVED	Reserved.	0x0	R
		0	INVALID_CFG_STATUS	Status bit indicating that TIMESLOT_PERIOD_x is not configured properly. Write 1 to this bit to clear this status.	0x0	R/W1C
0x0006	FIFO_TH	[15:10]	RESERVED	Reserved.	0x0	R
		[9:0]	FIFO_TH	FIFO interrupt generation threshold. This bit generates the FIFO interrupt during a FIFO write when the number of bytes in the FIFO exceeds this value.	0x0	R/W
0x0007	INT_ACLEAR	15	INT_ACLEAR_FIFO	FIFO threshold interrupt automatic clear enable. Set this bit to enable automatic clearing of the FIFO_TH bit interrupt each time the FIFO is read.	0x1	R/W
		[14:0]	RESERVED	Reserved.	0x0	R
0x0008	CHIP_ID	[15:8]	RESERVED	Reserved.	0x0	R
		[7:0]	CHIP_ID	Chip ID.	0xC4	R
0x0009	OSC32M	[15:8]	RESERVED	Reserved.	0x0	R
		[7:0]	OSC_32M_FREQ_ADJ	High frequency oscillator frequency control. 0x00 is the lowest frequency, and 0xFF is maximum frequency.	0x80	R/W

REGISTER DETAILS

Table 21. Register Details

Reg	Name	Bits	Bit Name	Description	Reset	Access
0x000A	OSC32M_CAL	15	OSC_32M_CAL_START	Start high frequency oscillator calibration cycle. Writing a 1 to this bit causes the high frequency oscillator calibration cycle to occur. 32 MHz oscillator cycles are counted during 128 low frequency oscillator cycles if using the 1 MHz low frequency oscillator, or 4 low frequency oscillator cycles if using the 32 kHz low frequency oscillator. The OSC_32M_CAL_COUNT bits are updated with the count. The calibration circuit clears the OSC_32M_CAL_START bit when the calibration cycle is completed. Silicon Version 0 counts 32 low frequency oscillator cycles if using the 32 kHz low frequency oscillator.	0x0	R/W
		[14:0]	OSC_32M_CAL_COUNT	High frequency oscillator calibration count. These bits contain the total number of 32 MHz cycles that occurred during the last high frequency oscillator calibration cycle.	0x0	R
0x000B	OSC960K	15	CAPTURE_TIMESTAMP	Enable time stamp capture. This bit field is used to activate the time stamp capture function. When set, the next rising edge on the time stamp input (defaults to GPIO0) causes a time stamp capture. This bit is cleared when the time stamp occurs.	0x0	R/W
		[14:11]	RESERVED	Reserved.	0x0	R
		10	OSC_CAL_ENABLE	Enable clock calibration clocking. Writing a 1 to this bit enables the clocking of the low frequency and high frequency calibration circuits.	0x0	R/W
		[9:0]	OSC_960K_FREQ_ADJ	Low frequency oscillator frequency control. 0x000 is the lowest frequency, and 0x3FF is maximum frequency.	0x2B2	R/W
0x000D	TS_FREQ	[15:0]	TIMESLOT_PERIOD_L	Lower 16 bits of time slot period in low frequency oscillator cycles. The time slot rate is (timer clock frequency)/(TIMESLOT_PERIOD_x). The default value operates at 100 Hz when using the 960 kHz clock. If the timer clock is set as an external source from the GPIO, either 960 kHz or 32 kHz, TM_CLK_GPIO_SEL must be configured to match the real clock frequency.	0x258 0	R/W
0x000E	TS_FREQH	[15:7]	RESERVED	Reserved.	0x0	R
		[6:0]	TIMESLOT_PERIOD_H	Upper seven bits of time slot period in low frequency oscillator cycles. The time slot rate is (timer clock frequency)/(TIMESLOT_PERIOD_x). The default value operates at 100 Hz when using the 960 kHz clock. If the timer clock is set to be an external source from the GPIO, either 960 kHz or 32 kHz, TM_CLK_GPIO_SEL must be configured to match the real clock frequency.	0x0	R/W
0x000F	SYS_CTL	15	SW_RESET	Software Reset. Write 1 to this bit to assert a software reset. This resets the chip to its default values and stops all AFE operations. The software reset does not reset the SPI (or optional I ² C) port.	0x0	R0/W
		[14:11]	RESERVED	Reserved.	0x0	R
		[10:8]	ALT_CLOCKS	External clock select. 000: use internal clocks. 001: use GPIO for low frequency oscillator (960 kHz). Timer clock also uses this as the source. 010: use GPIO for high frequency oscillator (32 MHz). 011: use GPIO for high frequency oscillator (32 MHz), and generate low frequency oscillator (1 MHz) from high frequency oscillator. This feature must be disabled when the ECG is enabled. 100: use GPIO for timer clock, 32 kHz or 960 kHz.	0x0	R/W
		[7:6]	ALT_CLK_GPIO	Alternate clock GPIO select.	0x0	R/W

REGISTER DETAILS

Table 21. Register Details

Reg	Name	Bits	Bit Name	Description	Reset	Access
0x0010	OPMODE			00: use GPIO0 for alternate clock. 01: use GPIO1 for alternate clock. 10: use GPIO2 for alternate clock. 11: reserved.		
		[5:3]	RESERVED	Reserved.	0x0	R
		2	TM_CLK_GPIO_SEL	Select low frequency clock between 960 kHz and 32 kHz. This bit must be used when ALT_CLOCKS is 3'b100. 0: use the 32 kHz external source from GPIO as the timer clock. 1: use the 960 kHz external source from GPIO as the low frequency clock.	0x0	R/W
		1	OSC_960K_EN	Enable low frequency oscillator. This bit turns on the 960 kHz low frequency oscillator, which must be left running during all operations using this oscillator.	0x0	R/W
		0	RESERVED	Reserved.	0x0	R
		15	ECG_TIMESLOT_EN	ECG time slot enable control. 0: disable ECG time slot. 1: enable ECG time slot.	0x0	R/W

0x02A7	BIOZ_DACCON_A	[15:14]	RESERVED	Reserved.	0x0	R
0x02C7	BIOZ_DACCON_B	13	BIOZ_EXBUFEN_x	Enable excitation buffer. Enable excitation buffer to drive the resistance under measurement. 0: disable. 1: enable.	0x0	R/W
0x02E7	BIOZ_DACCON_C					
0x0307	BIOZ_DACCON_D					
0x0327	BIOZ_DACCON_E	[12:10]	BIOZ_DACBUFBW_x	DAC reconstruction filter power consumption tuning. 001: 30 μA. 010: 40 μA. 100: 111 μA.	0x4	R/W
0x0347	BIOZ_DACCON_F					
		9	BIOZ_BW250KEN_x	Reconstruction filter cutoff frequency of 250 kHz.	0x1	R/W

REGISTER DETAILS

Table 21. Register Details

Reg	Name	Bits	Bit Name	Description	Reset	Access
				0: disable 250 kHz cutoff frequency. 1: enable 250 kHz cutoff frequency.		
		8	BIOZ_BW50KEN_x	Reconstruction filter cutoff frequency of 50 kHz. 0: disable 50 kHz cutoff frequency. 1: enable 50 kHz cutoff frequency.	0x0	R/W
		[7:0]	BIOZ_RATE_DIV_x	DAC update rate. DAC update rate = 32 MHz/ BIOZ_RATE_DIV_x.	0xD	R/W
0x02A8	BIOZ_DACGAIN_A	[15:13]	RESERVED	Reserved.	0x0	R
0x02C8	BIOZ_DACGAIN_B	12	BIOZ_DACGAIN_EN_x	Enable DAC gain.	0x1	R/W
0x02E8	BIOZ_DACGAIN_C			0: disable DAC gain correction.		
0x0308	BIOZ_DACGAIN_D			1: perform DAC gain correction.		
0x0328	BIOZ_DACGAIN_E					
0x0348	BIOZ_DACGAIN_F	[11:0]	BIOZ_DAC_GAIN_x	DAC gain correction factor. Unsigned number. 0x000: maximum negative gain adjustment occurs. 0x001: $1/2^{11}$. 0x800: no gain adjustment. 0xFF: maximum positive gain adjustment occurs.	0x800	R/W
0x02A9	BIOZ_DACOFFSET_A	[15:13]	RESERVED	Reserved.	0x0	R
0x02C9	BIOZ_DACOFFSET_B	12	BIOZ_DACOFFSET_EN_x	Bypass DAC offset. Use the DAC offset calculated during the calibration routine.	0x1	R/W
0x02E9	BIOZ_DACOFFSET_C			0: bypass DAC offset correction.		
0x0309	BIOZ_DACOFFSET_D			1: perform DAC offset correction.		
0x0329	BIOZ_DACOFFSET_E	[11:0]	BIOZ_DAC_OFFSET_x	DAC offset correction factor. Signed number represented in twos complement format with 0.5 LSB precision. Used when attenuator is disabled. Maximum positive adjustment. Results in positive full scale/ 2^{10} – 0.5 LSB adjustment. 0.5. results in 0.5 LSB adjustment 0. no offset adjustment. –0.5. results in –0.5 LSB adjustment. – 2^{10} . maximum negative adjustment. Results in negative full scale/2 adjustment.	0x0	R/W
0x0349	BIOZ_DACOFFSET_F					
0x02AA	BIOZ_ANA_CTRL1_A	[15:13]	BIOZ_TIA_RGAIN_x	Control signal for HPTIA feedback resistor.	0x1	R/W
0x02CA	BIOZ_ANA_CTRL1_B			000: 1 kΩ.		
0x02EA	BIOZ_ANA_CTRL1_C			001: 2 kΩ.		
0x030A	BIOZ_ANA_CTRL1_D			010: 3 kΩ.		
0x032A	BIOZ_ANA_CTRL1_E			011: 4 kΩ.		
0x034A	BIOZ_ANA_CTRL1_F			100: 6 kΩ.		
				101: 8 kΩ.		
		[12:9]	BIOZ_TIA_CGAIN_x	Control signal for HPTIA feedback capacitor. 0000: off. 0001: 1 pF. 0010: 2 pF. 0011: 3 pF. 0100: 4 pF (default value for low power). 0101: 5 pF. 0110: 6 pF. 0111: 7 pF (default value for high power). 1000: 8 pF. 1001: 9 pF.	0x7	R/W

REGISTER DETAILS

Table 21. Register Details

Reg	Name	Bits	Bit Name	Description	Reset	Access
				1010: 10 pF. 1011: 11 pF. 1100: 12 pF. 1101: 13 pF. 1110: 14 pF. 1111: 15 pF.		
		8	BIOZ_RX_LPMODE_x	Low power mode enable for ADC receiver channel. 0: high power mode. 1: low power mode.	0x0	R/W
		7	BIOZ_TIA_LPMODE_x	Low power mode enable for TIA. 0: high power mode. 1: low power mode.	0x0	R/W
		6	BIOZ_EXCBUF_LPMODE_x	Low power mode enable for excitation buffer. 0: high power mode. 1: low power mode.	0x0	R/W
		[5:4]	BIOZ_CHOP_OFF_IN_x	Disable chop off front buffer and PGA. 00: enable front buffer and PGA chopping. 01: only enable PGA chopping. 10: only enable front buffer chopping. 11: disable front buffer and PGA chopping.	0x3	R/W
		[3:2]	BIOZ_AMP_OFF_x	Disable front buffer. 00: enable all. 01: only enable Buffer_p 10: only enable Buffer_n. 11: disable Buffer_p and Buffer_n.	0x3	R/W
		1	BIOZ_PGA_PD_x	PGA P _D control. 0: enable. 1: disable.	0x1	R/W
		0	BIOZ_DAC_RCF_LOWBW_EN_x	DAC RC filters bandwidth tuning. High to set bandwidth reduced to 80% of its original value. 0: disable. 1: enable.	0x0	R/W
0x02AB	BIOZ_ANA_CTRL2_A	15	RESERVED	Reserved.	0x0	R
0x02CB	BIOZ_ANA_CTRL2_B	14	BIOZ_CM_SW_x	Weak V _{CM} driven for IMPIP and IMPIN. 0: disable weak V _{CM} driven. 1: weak CM driven IMPIP and IMPIN.	0x0	R/W
0x02EB	BIOZ_ANA_CTRL2_C					
0x030B	BIOZ_ANA_CTRL2_D	[13:12]	BIOZ_NCHAN_x	N-channel selection. 00: connect HPTIA_n to Buffer_p. 01: connect IMPIN to Buffer_n. 10: connect RCALN to Buffer_n. 11: connect R _{INT_SN} to Buffer_n.	0x0	R/W
0x032B	BIOZ_ANA_CTRL2_E					
0x034B	BIOZ_ANA_CTRL2_F					
		[11:10]	BIOZ_PCHAN_x	P-channel selection. 00: connect HPTIA_p to Buffer_p. 01: connect IMPIP to Buffer_p. 10: connect RCALP to Buffer_p. 11: connect R _{INT_SP} to Buffer_p.	0x0	R/W
		[9:6]	BIOZ_TSW_x	Switch mux for TIA input. 0001: connect TIA input to IMPIP.	0x0	R/W

REGISTER DETAILS

Table 21. Register Details

Reg	Name	Bits	Bit Name	Description	Reset	Access
				0010: connect TIA input to IMPIN. 0100: connect TIA input to EXCP. 1000: connect TIA input to EXCN.		
		[5:2]	BIOZ_DSW_x	Switch mux for excitation buffer output. 0001: connect excitation buffer output to IMPIP. 0010: connect excitation buffer output to IMPIN. 0100: connect excitation buffer output to EXCP. 1000: connect excitation buffer output to EXCN.	0x0	R/W
		1	BIOZ_TRSW_x	T switch in mux for RCALx. 0: disconnect RCALx to HPTIA. 1: connect RCALx to HPTIA.	0x0	R/W
		0	BIOZ_DRSW_x	D switch in mux for RCALx. 0: disconnect RCALx to excitation buffer. 1: connect RCALx to excitation buffer.	0x0	R/W
0x02AC	BIOZ_ANA_CTRL3_A	[15:2]	RESERVED	Reserved.	0x0	R
0x02CC	BIOZ_ANA_CTRL3_B	[1:0]	BIOZ_RINT_SW_x	Support internal calibration resistor. Set to 0x11 to enable the internal calibration resolution. 00: floating internal calibration resistance. 11: connect internal calibration resistance to excitation buffer and HPTIA.	0x0	R/W
0x02EC	BIOZ_ANA_CTRL3_C					
0x030C	BIOZ_ANA_CTRL3_D					
0x032C	BIOZ_ANA_CTRL3_E
