

1.5GHz to 2.5GHz Direct Conversion Quadrature Demodulator

FEATURES

- Frequency Range: 1.5GHz to 2.5GHz
- High IIP3: 20dBm at 1.9GHz
- High IIP2: 51dBm at 1.9GHz
- Noise Figure: 16.8dB at 1.9GHz
- Conversion Gain: -0.7dB at 1.9GHz
- I/Q Gain Mismatch: 0.3dB
- I/Q Phase Mismatch: 1°
- Shutdown Mode
- 16-Lead QFN 4mm × 4mm Package with Exposed Pad

APPLICATIONS

- Cellular/PCS/UMTS Infrastructure
- High Linearity Direct Conversion I/Q Receiver
- High Linearity I/Q Demodulator
- RF Power Amplifier Linearization

DESCRIPTION

The LT[®]5515 is a 1.5GHz to 2.5GHz direct conversion quadrature demodulator optimized for high linearity receiver applications. It is suitable for communications receivers where an RF signal is directly converted into I and Q baseband signals with bandwidth up to 260MHz. The LT5515 incorporates balanced I and Q mixers, LO buffer amplifiers and a precision, high frequency quadrature generator.

In an RF receiver, the high linearity of the LT5515 provides excellent spur-free dynamic range, even with fixed gain front end amplification. This direct conversion receiver can eliminate the need for intermediate frequency (IF) signal processing, as well as the corresponding requirements for image filtering and IF filtering. Channel filtering can be performed directly at the outputs of the I and Q channels. These outputs can interface directly to channel-select filters (LPFs) or to a baseband amplifier.

LT, LTC and LTM are registered trademarks of Linear Technology Corporation. All other trademarks are the property of their respective owners.

PIN FUNCTIONS

GND (Pins 1, 4): Ground Pin.

RF⁺, RF⁻ (Pins 2, 3): Differential RF Input Pins. These pins are internally biased to 1.54V. They must be driven with a differential signal. An external matching network is required for impedance transformation.

V_{CC} (Pins 5, 8, 9, 12): Power Supply Pins. These pins should be decoupled using 1000pF and 0.1μF capacitors.

V_{CM} (Pin 6): Common Mode and DC Return for the I-Mixer and Q-Mixer. An external resistor must be connected between this pin and ground to set the DC bias current of the I/Q demodulator.

EN (Pin 7): Enable Pin. When the input voltage is higher than 1.6V, the circuit is completely turned on. When the input voltage is less than 1.3V, the circuit is turned off.

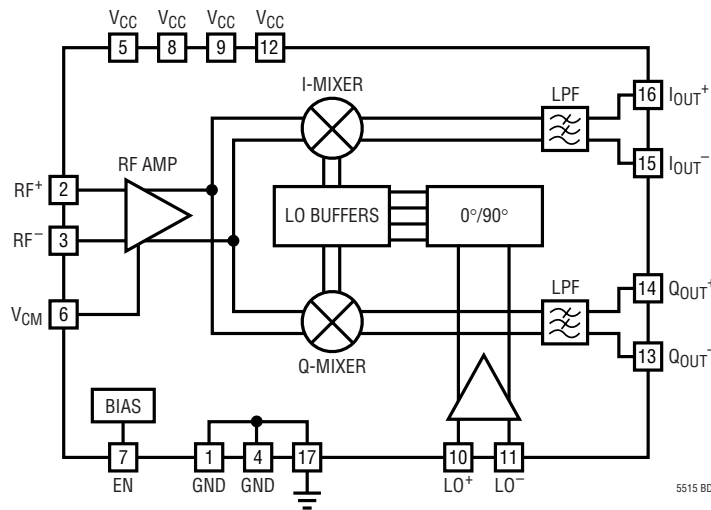

LO⁺, LO⁻ (Pins 10, 11): Differential Local Oscillator Input Pins. These pins are internally biased to 2.44V. They can be driven single-ended by connecting one to an AC ground through a 1000pF capacitor. However, differential input drive is recommended to minimize LO feedthrough to the RF input pins.

Q_{OUT}⁻, Q_{OUT}⁺ (Pins 13, 14): Differential Baseband Output Pins of the Q-Channel. The internal DC bias voltage is V_{CC} - 0.85V for each pin.

I_{OUT}⁻, I_{OUT}⁺ (Pins 15, 16): Differential Baseband Output Pins of the I-Channel. The internal DC bias voltage is V_{CC} - 0.85V for each pin.

GROUND (Pin 17, Backside Contact): Ground Return for the Entire IC. This pin must be soldered to the printed circuit board ground plane.

APPLICATIONS INFORMATION

The LT5515 is a direct I/Q demodulator targeting high linearity receiver applications, including wireless infrastructure. It consists of an RF amplifier, I/Q mixers, a quadrature LO carrier generator and bias circuitry.

The RF signal is applied to the inputs of the RF amplifier and is then demodulated into I/Q baseband signals using quadrature LO signals. The quadrature LO signals are internally generated by precision 90° phase shifters. The demodulated I/Q signals are lowpass filtered internally with a –3dB bandwidth of 260MHz. The differential outputs of the I-channel and Q-channel are well matched in amplitude; their phases are 90° apart.

RF Input Port

Differential drive is highly recommended for the RF inputs to minimize the LO feedthrough to the RF port and to maximize gain. (See Figure 2.) A 1:4 transformer is used on the demonstration board for wider bandwidth matching. To assure good NF and maximize the demodulator gain, a low loss transformer is employed. Shunt inductor L1, with high resonance frequency, is required for proper impedance matching. Single-ended to differential conversion can also be implemented using narrow band, discrete L-C circuits to produce the required balanced waveforms at the RF+ and RF- inputs. The differential impedance of the RF inputs is listed in Table 1.

Table 1. RF Input Differential Impedance

FREQUENCY (GHz)	DIFFERENTIAL INPUT IMPEDANCE (Ω)	DIFFERENTIAL S11	
		MAG	ANGLE(°)
1.5	115.7-j132.7	0.698	-24.9
1.6	111.7-j128.1	0.689	-25.9
1.7	108.1-j123.7	0.681	-26.8
1.8	104.8-j120.2	0.674	-27.7
1.9	101.7-j116.9	0.667	-28.5
2.0	98.8-j113.8	0.661	-29.4
2.1	96.0-j111.1	0.655	-30.2
2.2	93.3-j108.7	0.650	-31.1
2.3	90.7-j106.2	0.645	-32.0
2.4	88.3-j104.2	0.641	-32.8
2.5	85.9-j102.2	0.637	-33.7

The RF+ and RF- inputs (Pins 2, 3) are internally biased at 1.54V. These two pins should be DC blocked when connected to ground or other matching components. The RF input equivalent circuit is shown in Figure 5.

A 4.3Ω resistor (R1) is connected to Pin 6 (V_{CM}) to set the optimum DC current for I/Q mixer linearity. The trade-off of the NF and IIP3 as a function of R1 is shown in the “Typical Performance Characteristics”. When a smaller R1 is used for better linearity, the total supply current will increase. A 5V ±5% power supply is recommended to assure high linearity performance.

LO Input Port

The LO inputs (Pins 10,11) should be driven differentially to minimize LO feedthrough to the RF port. This can be accomplished by means of a single-ended to differential conversion as shown in Figure 2. L4, the 12nH shunt inductor, serves to tune out the capacitive component of the LO differential input. The resonance frequency of the inductor should be greater than the operating frequency. A 1:2 transformer is used on the demo board to match the LO port to a 50Ω source. Figure 6 shows the LO input equivalent circuit and the associated matching network.

Single-ended to differential conversion at the LO inputs can also be implemented using a discrete L-C circuit to produce a balanced waveform without a transformer.

An alternative solution is a simple single-ended termination. However, the LO feedthrough to RF may be degraded. Either LO+ or LO- input can be terminated to a 50Ω source with a matching circuit, while the other input is connected to ground through a 100pF bypass capacitor.

APPLICATIONS INFORMATION

Table 2 shows the differential input impedance of the LO input port.

Table 2. LO Input Differential Impedance

FREQUENCY (GHz)	DIFFERENTIAL INPUT IMPEDANCE (Ω)	DIFFERENTIAL S11	
		MAG	ANGLE ($^{\circ}$)
1.5	69.3-j59.4	0.469	-45.8
1.6	64.3-j56.4	0.457	-49.8
1.7	60.0-j52.7	0.440	-53.9
1.8	56.4-j48.9	0.421	-58.0
1.9	53.7-j44.9	0.399	-62.2
2.0	51.4-j41.2	0.377	-66.1
2.1	49.8-j37.5	0.352	-69.9
2.2	48.6-j34.2	0.328	-73.3
2.3	47.8-j31.0	0.303	-76.5
2.4	47.3-j28.2	0.279	-79.5
2.5	46.9-j25.6	0.257	-82.3

I-Channel and Q-Channel Outputs

Each of the I-channel and Q-channel outputs is internally connected to V_{CC} through a 60Ω resistor. The output DC bias voltage is $V_{CC} - 0.85V$. The outputs can be DC coupled or AC coupled to the external loads. The differential output impedance of the demodulator is 120Ω in parallel with a $5pF$ internal capacitor, forming a lowpass filter with a $-3dB$ corner frequency at $260MHz$. R_{LOAD} (the single-

ended load resistance) should be larger than 600Ω to assure full gain. The gain is reduced by $20 \cdot \log(1 + 120\Omega/R_{LOAD})$ in dB when the differential output is terminated by R_{LOAD} . For instance, the gain is reduced by $6.85dB$ when each output pin is connected to a 50Ω load (100Ω differential load). The output should be taken differentially (or by using differential-to-single-ended conversion) for best RF performance, including NF and IM2.

The phase relationship between the I-channel output signal and Q-channel output signal is fixed. When the LO input frequency is larger (or smaller) than the RF input frequency, the Q-channel outputs (Q_{OUT+} , Q_{OUT-}) lead (or lag) I-channel outputs (I_{OUT+} , I_{OUT-}) by 90° .

When AC output coupling is used, the resulting highpass filter's $-3dB$ roll-off frequency is defined by the R-C constant of the blocking capacitor and R_{LOAD} , assuming $R_{LOAD} > 600\Omega$.

Care should be taken when the demodulator's outputs are DC coupled to the external load, to make sure that the I/Q mixers are biased properly. If the current drain from each output exceeds $6mA$, there can be significant degradation of the linearity performance. Each output can sink no more than $14mA$ when the outputs are connected to an external load with a DC voltage higher than $V_{CC} - 0.85V$. The I/Q output equivalent circuit is shown in Figure 7.
