

LT5527

FEATURES

- ⁿ **50Ω Single-Ended RF and LO Ports**
- ⁿ **Wide RF Frequency Range: 400MHz to 3.7GHz***
- ⁿ **High Input IP3: 24.5dBm at 900MHz 23.5dBm at 1900MHz**
- ⁿ **Conversion Gain: 3.2dB at 900MHz 2.3dB at 1900MHz**
- Integrated LO Buffer: Low LO Drive Level
- ⁿ **High LO-RF and LO-IF Isolation**
- Low Noise Figure: 11.6dB at 900MHz 12.5dB at 1900MHz
- Very Few External Components
- **Enable Function**
- 4.5V to 5.25V Supply Voltage Range
- **16-Lead (4mm** \times **4mm) QFN Package**

APPLICATIONS

- Cellular, WCDMA, TD-SCDMA and UMTS **Infrastructure**
- GSM900/GSM1800/GSM1900 Infrastructure
- \blacksquare 900MHz/2.4GHz/3.5GHz WLAN
- **NMDS, WIMAX**
- High Linearity Downmixer Applications

TYPICAL APPLICATION

High Signal Level Downmixer for Multi-Carrier Wireless Infrastructure 1.9GHz Conversion Gain, IIP3, SSB NF and

DESCRIPTION 400MHz to 3.7GHz 5V High Signal Level Downconverting Mixer

The LT®5527 active mixer is optimized for high linearity, wide dynamic range downconverter applications. The IC includes a high speed differential LO buffer amplifier driving a double-balanced mixer. Broadband, integrated transformers on the RF and LO inputs provide single-ended 50Ω interfaces. The differential IF output allows convenient interfacing to differential IF filters and amplifiers, or is easily matched to drive 50Ω single-ended, with or without an external transformer.

The RF input is internally matched to 50Ω from 1.7GHz to 3GHz, and the LO input is internally matched to 50Ω from 1.2GHz to 5GHz. The frequency range of both ports is easily extended with simple external matching. The IF output is partially matched and usable for IF frequencies up to 600MHz.

The LT5527's high level of integration minimizes the total solution cost, board space and system-level variation.

AC ELECTRICAL CHARACTERISTICS Test circuit shown in Figure 1. (Notes 2, 3)

Standard Downmixer Application: V_{CC} = 5V, EN = High, T_A = 25°C, P_{RF} = –5dBm (–5dBm/tone for 2-tone IIP3 tests, Δf = 1MHz), f_{LO} = f_{RF} – f_{IF}, P_{LO} = –3dBm (OdBm for 450MHz and 900MHz tests), IF output measured at 240MHz, unless otherwise noted. Test circuit shown **in Figure 1. (Notes 2, 3, 4)**

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.

Note 2: 450MHz, 900MHz and 3500MHz performance measured with external LO and RF matching. See Figure 1 and Applications Information. **Note 3:** Specifications over the -40° C to 85°C temperature range are assured by design, characterization and correlation with statistical process controls.

Note 4: SSB Noise Figure measurements performed with a small-signal noise source and bandpass filter on RF input, and no other RF signal applied.

TYPICAL AC PERFORMANCE CHARACTERISTICS Midband (No external RF/LO matching)

V_{CC} = 5V, EN = High, P_{RF} = –5dBm (–5dBm/tone for 2-tone IIP3 tests, Δf = 1MHz), P_{LO} = –3dBm, IF output measured at 240MHz, unless **otherwise noted. Test circuit shown in Figure 1.**

TYPICAL AC PERFORMANCE CHARACTERISTICS Midband (No external RF/LO matching)

V_{CC} = 5V, EN = High, P_{RF} = –5dBm (–5dBm/tone for 2-tone IIP3 tests, Δf = 1MHz), P_{LO} = –3dBm, IF output measured at 240MHz, unless **otherwise noted. Test circuit shown in Figure 1.**

High Band (3500MHz application with external RF matching) V_{CC} = 5V, EN = High, P_{RF} = -5dBm (-5dBm/tone for 2-tone IIP3 tests, **Δf = 1MHz), low side LO, PLO = –3dBm, IF output measured at 380MHz, unless otherwise noted. Test circuit shown in Figure 1.**

TYPICAL AC PERFORMANCE CHARACTERISTICS Low Band (900MHz application with external

RF/LO matching) V_{CC} = 5V, EN = High, P_{RF} = –5dBm (–5dBm/tone for 2-tone IIP3 tests, Δf = 1MHz), P_{LO} = 0dBm, IF output measured at **140MHz, unless otherwise noted. Test circuit shown in Figure 1.**

TYPICAL DC PERFORMANCE CHARACTERISTICS Test circuit shown in Figure 1.

PIN FUNCTIONS

NC(Pins 1, 2, 4, 8, 13, 14, 16): Not Connected Internally. These pins should be grounded on the circuit board for improved LO-to-RF and LO-to-IF isolation.

RF (Pin 3): Single-Ended Input for the RF Signal. This pin is internally connected to the primary side of the RF input transformer, which has low DC resistance to ground. **If the RF source is not DC blocked, then a series blocking capacitor must be used**. The RF input is internally matched from 1.7GHz to 3GHz. Operation down to 400MHz or up to 3700MHz is possible with simple external matching.

EN (Pin 5): Enable Pin. When the input enable voltage is higher than 3V, the mixer circuits supplied through Pins 6, 7, 10 and 11 are enabled. When the input voltage is less than 0.3V, all circuits are disabled. Typical input current is 50μA for $EN = 5V$ and $Q\mu A$ when $EN = 0V$. The EN pin should not be left floating. Under no conditions should the EN pin voltage exceed V_{CC} + 0.3V, even at start-up.

V_{CC2} (Pin 6): Power Supply Pin for the Bias Circuits. Typical current consumption is 2.8mA. This pin should be externally connected to the V_{CG1} pin and decoupled with 1000pF and 1μF capacitors.

V_{CC1} (Pin 7): Power Supply Pin for the LO Buffer Circuits. Typical current consumption is 23.2mA. This pin should be externally connected to the V_{CC2} pin and decoupled with 1000pF and 1µF capacitors.

GND (Pins 9, 12): Ground. These pins are internally connected to the backside ground for improved isolation. They should be connected to the RF ground on the circuit board, although they are not intended to replace the primary grounding through the backside contact of the package.

IF–, IF+ (Pins 10, 11): Differential Outputs for the IF Signal. An impedance transformation may be required to match the outputs. These pins must be connected to V_{CC} through impedance matching inductors, RF chokes or a transformer center tap.

LO (Pin 15): Single-Ended Input for the Local Oscillator Signal. This pin is internally connected to the primary side of the LO transformer, which is internally DC blocked. An external blocking capacitor is not required. The LO input is internally matched from 1.2GHz to 5GHz. Operation down to 380MHz is possible with simple external matching.

Exposed Pad (Pin 17): Circuit Ground Return for the Entire IC. This must be soldered to the printed circuit board ground plane.

Figure 2. Downmixer Test Schematic—Discrete IF Balun Matching (240MHz IF)

Introduction

The LT5527 consists of a high linearity double-balanced mixer. RF buffer amplifier, high speed limiting LO buffer amplifier and bias/enable circuits. The RF and LO inputs are both single ended. The IF output is differential. Low side or high side LO injection can be used.

Two evaluation circuits are available. The standard evaluation circuit, shown in Figure 1, incorporates transformerbased IF matching and is intended for applications that require the lowest LO-IF leakage levels and the widest IF bandwidth. The second evaluation circuit, shown in Figure 2, replaces the IF transformer with a discrete IF balun for reduced solution cost and size. The discrete IF balun delivers comparable noise figure and linearity, higher conversion gain, but degraded LO-IF leakage and reduced IF bandwidth.

RF Input Port

The mixer's RF input, shown in Figure 3, consists of an integrated transformer and a high linearity differential amplifier. The primary terminals of the transformer are connected to the RF input pin (Pin 3) and ground. The secondary side of the transformer is internally connected to the amplifier's differential inputs.

One terminal of the transformer's primary is internally grounded. If the RF source has DC voltage present, then a coupling capacitor must be used in series with the RF input pin.

The RF input is internally matched from 1.7GHz to 3GHz, requiring no external components over this frequency range. The input return loss, shown in Figure 4a, is typically 10dB at the band edges. The input match at the lower band edge can be optimized with a series 2.7pF capacitor

at Pin 3, which improves the 1.7GHz return loss to greater than 20dB. Likewise, the 2.7GHz match can be improved to greater than 30dB with a series 1.5nH inductor. A series 1.5nH/2.7pF network will simultaneously optimize the lower and upper band edges and expand the RF input bandwidth to 1.1GHz-3.3GHz. Measured RF input return losses for these three cases are also plotted in Figure 4a.

Alternatively, the input match can be shifted down, as low as 400MHz or up to 3700MHz, by adding a shunt capacitor (C5) to the RF input. A 450MHz input match is realized with C5 = 12pF, located 4.5mm away from Pin 3 on the evaluation board's 50Ω input transmission line. A 900MHz input match requires C5 = 3.9pF, located at 1.3mm. A 3500MHz input match is realized with $C5 = 0.5pF$, located at 4.5mm. This

(4a) Series Reactance Matching

(4b) Series Shunt Matching

Figure 3. RF Input Schematic Figure 4. RF Input Return Loss With and Without External Matching

series transmission line/shunt capacitor matching topology allows the LT5527 to be used for multiple frequency standards without circuit board layout modifications. The series transmission line can also be replaced with a series chip inductor for a more compact layout.

Input return loss for these three cases (450MHz, 900MHz and 3500MHz) are plotted in Figure 4b. The input return loss with no external matching is repeated in Figure 4b for comparison.

RF input impedance and S11 versus frequency (with no external matching) is listed in Table 1 and referenced to Pin 3. The S11 data can be used with a microwave circuit simulator to design custom matching networks and simulate board-level interfacing to the RF input filter.

Table 1. RF Input Impedance vs Frequency

LO Input Port

The mixer's LO input, shown in Figure 5, consists of an integrated transformer and high speed limiting differential amplifiers. The amplifiers are designed to precisely drive the mixer for the highest linearity and the lowest noise figure. An internal DC blocking capacitor in series with the transformer's primary eliminates the need for an external blocking capacitor.

The LO input is internally matched from 1.2GHz to 5GHz, although the maximum useful frequency is limited to 3.5GHz by the internal amplifiers. The input match can be shifted down, as low as 750MHz, with a single shunt capacitor (C4) on Pin 15. One example is plotted in Figure 6 where C4 = 2.7pF produces an 850MHz to 1.2GHz match.

LO input matching below 750MHz requires the series inductor (L4)/shunt capacitor (C4) network shown in Figure 5. Two examples are plotted in Figure 6 where L4 = 3.9nH/C4 $= 5.6$ pF produces a 650MHz to 830MHz match and L4 $=$ 6.8nH/C4 = 10pF produces a 540MHz to 640MHz match. The evaluation boards do not include pads for L4, so the circuit trace needs to be cut near Pin 15 to insert L4. A low cost multilayer chip inductor is adequate for L4.

The optimum LO drive is –3dBm for LO frequencies above 1.2GHz, although the amplifiers are designed to accommodate several dB of LO input power variation without significant mixer performance variation. Below 1.2GHz,

Figure 6. LO Input Return Loss

0dBm LO drive is recommended for optimum noise figure, although –3dBm will still deliver good conversion gain and linearity.

Custom matching networks can be designed using the port impedance data listed in Table 2. This data is referenced to the LO pin with no external matching.

Table 2. LO Input Impedance vs Frequency

IF Output Port

The IF outputs, IF+ and IF–, are internally connected to the collectors of the mixer switching transistors (see Figure 7). Both pins must be biased at the supply voltage, which can be applied through the center tap of a transformer or through matching inductors. Each IF pin draws 26mA of supply current (52mA total). For optimum single-ended performance, these differential outputs should be combined externally through an IF transformer or a discrete IF balun circuit. The standard evaluation board (see Figure 1) includes an IF transformer for impedance transformation and differential to single-ended transformation. A second evaluation board (see Figure 2) realizes the same functionality with a discrete IF balun circuit.

The IF output impedance can be modeled as 415Ω in parallel with 2.5pF at low frequencies. An equivalent small-signal model (including bondwire inductance) is shown in Figure

8. Frequency-dependent differential IF output impedance is listed in Table 3. This data is referenced to the package pins (with no external components) and includes the effects of IC and package parasitics. The IF output can be matched for IF frequencies as low as several kHz or as high as 600MHz.

The following three methods of differential to single-ended IF matching will be described:

- Direct 8:1 transformer
- Lowpass matching $+4:1$ transformer
- Discrete IF balun

Figure 7. IF Output with External Matching

Figure 8. IF Output Small-Signal Model

Direct 8:1 IF Transformer Matching

For IF frequencies below 100MHz, the simplest IF matching technique is an 8:1 transformer connected across the IF pins. The transformer will perform impedance transformation and provide a single-ended 50Ω output. No other matching is required. Measured performance using this technique is shown in Figure 9. This matching is easily implemented on the standard evaluation board by shorting across the pads for L1 and L2 and replacing the 4:1 transformer with an 8:1 (C3 not installed).

Figure 9. Typical Conversion Gain, IIP3 and SSB NF Using an 8:1 IF Transformer

Lowpass + 4:1 IF Transformer Matching

The lowest LO-IF leakage and wide IF bandwidth are realized by using the simple, three element lowpass matching network shown in Figure 7. Matching elements C3, L1 and L2, in conjunction with the internal 2.5pF capacitance, form a 400 Ω to 200 Ω lowpass matching network which is tuned to the desired IF frequency. The 4:1 transformer then transforms the 200 Ω differential output to a 50 Ω single-ended output.

This matching network is most suitable for IF frequencies above 40MHz or so. Below 40MHz, the value of the series inductors (L1 and L2) becomes unreasonably high, and could cause stability problems, depending on the inductor value and parasitics. Therefore, the 8:1 transformer technique is recommended for low IF frequencies.

Suggested lowpass matching element values for several IF

frequencies are listed in Table 4. High-Q wire-wound chip inductors (L1 and L2) improve the mixer's conversion gain by a few tenths of a dB, but have little effect on linearity. Measured output return losses for each case are plotted in Figure 10 for the simple 8:1 transformer method and for the lowpass/4:1 transformer method.

Figure 10. IF Output Return Losses with Lowpass/Transformer Matching

Discrete IF Balun Matching

For many applications, it is possible to replace the IF transformer with the discrete IF balun shown in Figure 2. The values of L1, L2, C6 and C7 are calculated to realize a 180 degree phase shift at the desired IF frequency and provide a 50 Ω single-ended output, using the equations listed below. Inductor L3 is calculated to cancel the internal 2.5pF capacitance. L3 also supplies bias voltage to the IF+ pin. Low cost multilayer chip inductors are adequate for L1 and L2. A high Q wire-wound chip inductor is recommended for L3 to maximize conversion gain and minimize DC voltage drop to the IF+ pin. C3 is a DC blocking capacitor.

$$
L1, L2 = \frac{\sqrt{R_{IF} \cdot R_{OUT}}}{\omega_{IF}}
$$

$$
C6, C7 = \frac{1}{\omega_{IF} \cdot \sqrt{R_{IF} \cdot R_{OUT}}}
$$

$$
L3 = \frac{|X_{IF}|}{\omega_{IF}}
$$

Compared to the lowpass/4:1 transformer matching technique, this network delivers approximately 0.8dB higher conversion gain (since the IF transformer loss is eliminated) and comparable noise figure and IIP3. At a $\pm 15\%$ offset from the IF center frequency, conversion gain and noise figure degrade about 1dB. Beyond ± 15 %, conversion gain decreases gradually but noise figure increases rapidly. IIP3 is less sensitive to bandwidth. Other than IF bandwidth, the most significant difference is LO-IF leakage, which degrades to approximately –38dBm compared to the superior performance realized with the lowpass/4:1 transformer matching.

Discrete IF balun element values for four common IF frequencies are listed in Table 5. The corresponding measured IF output return losses are shown in Figure 11. The values listed in Table 5 differ from the calculated values slightly due to circuit board and component parasitics. Typical conversion gain, IIP3 and LO-IF leakage, versus RF input frequency, for all four IF frequency examples is shown in Figure 12. Typical conversion gain, IIP3 and noise figure versus IF output frequency for the same circuits are shown in Figure 13.

For fully differential IF architectures, the IF transformer can be eliminated. An example is shown in Figure 14, where the mixer's IF output is matched directly into a SAW filter. Supply voltage to the mixer's IF pins is applied through

Figure 11. IF Output Return Losses with Discrete Balun Matching

Figure 12. Conversion Gain, IIP3 and LO-IF Leakage vs RF Input Frequency Using Discrete IF Balun Matching

Figure 13. Conversion Gain, IIP3 and SSB NF vs IF Output Frequency Using Discrete IF Balun Matching

matching inductors in a band-pass IF matching network. The values of L1, L2 and C3 are calculated to resonate at the desired IF frequency with a quality factor that satisfies the required IF bandwidth. The L and C values are then adjusted to account for the mixer's internal 2.5pF capacitance and the SAW filter's input capacitance. In this case, the differential IF output impedance is 400Ω since the bandpass network does not transform the impedance.

Additional matching elements may be required if the SAW filter's input impedance is less than or greater than 400 Ω . Contact the factory for application assistance.
